77860 Density change of glassy $\text{Pd}_{77}\text{Si}_{16.5}\text{Cu}_{6.5}$ alloy during cold drawing. Deguo Deng, Banghong Lu (Inst. of Precious Metals, Kunming, Yunnan, China).

Ser. Metall. (USA), vol.17, no.4, p.515-18 (April 1983).

Reports the results of density change experiments using thick $\text{Pd}_{77}\text{Si}_{16.5}\text{Cu}_{6.5}$ glassy wires, and compares them with various theories and experiments. The general trend of the results is consistent with those of Megusar et al. (1981). (9 refs.)

77861 Current research in adhesiveless bonding of cover glasses to solar cells. D.W.Egelkrut, A.C.Day, W.E.Horne (Boeing Aerospace Co., Seattle, WA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.108-14

Reviews recent research on electrostatic bonding of cover glasses to newly developed high temperature solar cells. Although high temperature solar cells were developed to withstand temperature excursions up to 700°C for about 1 to 15 minutes, a newly discovered damage mechanism causes severe degradation of these cells during the ESB process at temperatures of only 550°C in 4 to 6 minutes. The damage was found to be the result of a synergistic effect of the electric fields and temperatures used in the ESB process. The theory for this process is presented and a solution is proposed and partially demonstrated. Also, a process called field assisted laser bonding has been investigated. The process utilizes rapid heating of cover glasses by 10.6 μm laser energy in combination with electric fields to produce bonding. The use of a potential grid to distribute the electric field is described and a reaction observed between the grid and glass is discussed. (17 refs.)

77862 Quantum chemical and statistical-thermodynamic studies of equilibria and rates. R.Zahradnik (J. Heyrovsky Inst. of Phys. Chem. & Electrochem., Acad. of Sci., Prague, Czechoslovakia). *Pure & Appl. Chem. (GB)*, vol.55, no.2, p.391-400 (Feb. 1983). (International Symposium on Theoretical Organic Chemistry, Dubrovnik, Croatia, Yugoslavia, 30 Aug.-3 Sept. 1982).

A review of the main results from the author's laboratory for the period 1969-1982 is presented. In the introductory part, allowed and forbidden processes are discussed from the point of view of constants of motion. Specific suggestions are presented as to how to make forbidden processes allowed. In addition to energy forbiddenness, entropy forbiddenness is also mentioned. In the section on equilibria attempts to locate minima of potential energy surfaces (PES), and statistical-thermodynamic calculations of equilibrium constants for common and van der Waals molecules, are summarized. Then information follows on the location of saddle points on PES, reaction coordinates and statistical-thermodynamic calculations of rate constants of elementary reactions. The final section deals with studies of catalytic reactions. (69 refs.)

77863 A comparison of various MO methods for predicting regioselectivity in Diels-Alder reactions. Chen Zhixing (Chem. Dept., Zhongshan Univ., Guangzhou, China). *Theor. Chim. Acta (Germany)*, vol.62, no.4, p.293-9 (1983).

Various semiempirical MO methods for predicting regioselectivity in Diels-Alder reactions are compared in order to examine their reliability. They are the frontier molecular orbital method using CNDO/2, HMO and MNDO molecular orbitals and the HMO approach on pericyclic reactions presented by A. Tang (1975). (14 refs.)

77864 Topography of potential energy surfaces. M.V.Basilevsky (Karpov Inst. of Phys. Chem., Moscow, USSR). *Pure & Appl. Chem. (GB)*, vol.55, no.2, p.207-12 (Feb. 1983). (International Symposium on Theoretical Organic Chemistry, Dubrovnik, Croatia, Yugoslavia, 30 Aug.-3 Sept. 1982).

The curves on a multi-dimensional potential energy surface (PES) linking the reactant and the transition state configurations are constructed. They are generally distinct from usual reaction path curves and a special term 'optimum ascent path' (OAP) is accepted for them. A local criterion is formulated allowing one to distinguish the points located on an OAP among other points in its vicinity. A mathematical analysis of singular points of a PES, where its

valleys or ridges emerge, dissipate or bifurcate, is presented. These points are specified as different branching points of OAPs. (11 refs.)

77865 Effects of diffusion on long-range electron transfer. A.M.Kuznetsov (Inst. of Electrochem., Acad. of Sci., Moscow, USSR), J.Ulstrup. *Chem. Phys. Lett. (Netherlands)*, vol.97, no.3, p.285-91 (20 May 1983). The competition between diffusive hops and direct tunnelling of solvated electrons to scavenger molecules in solid glasses has been discussed in the literature. The authors have considered these two reaction paths in terms of stationary kinetic diffusion equations and multiphonon electron-transfer rate theory, and for coupling of the solvated electron to a broad continuum of nuclear modes. Diffusion can only be expected to be important for less polar glasses. (34 refs.)

82.30 SPECIFIC CHEMICAL REACTIONS; REACTION MECHANISMS

77866 Decomposition kinetics of iodine monochloride in shock waves. Zhang Rongyao, Sha Guohe, Han Denglong, Wang Yimin, Zhang Cunhao. *Acta Mech. Sin. (China)*, no.2, p.203-5 (1983). In Chinese. The decomposition kinetics of ICl in Ar mixture have been studied in a shock tube over the temperature range 1000 to 2000K. Dual absorption spectrophotometry is used to follow the course of the reaction. A rate constant correlation given by $k_1 = 1.21 \times 10^{12} \exp(-35.8 \times 10^3/RT)$ cm³/mole. sec is obtained to fit the measured data. The heteroatom recombination $I+Cl+Ar \rightarrow ICl+Ar$ is about a factor of 10 faster than the homoatom recombination $I+I+Ar \rightarrow I_2+Ar$ with a larger negative temperature coefficient. Both facts can be reasonably interpreted in terms of a plausible pathway proceeding via the Cl-Ar complex. (8 refs.)

77867 The mechanism of carbonyl reduction by $LiBH_4$: an ab initio investigation with inclusion of solvent effects. R.Bonaccorsi (Istituto di Chimica Quantistica ed Energetica Molecolare, CNR, Pisa, Italy), R.Cimiraglia, J.Tomasi, S.Miertus. *THEOCHEM (Netherlands)*, vol.11, no.1-2, p.11-23 (June 1983). The mechanism of the reaction $H_2CO+LiBH_4 \rightarrow$ products has been investigated by using SCF calculations in a modified formalism which includes solvent effects. The effects of the solvent are represented by a one-electron operator added to the Fock Hamiltonian of the molecular system. The influence of the solvent on the reaction energy profile, on the geometry of the transition state, intermediate species, reagents and products is brought out by comparing the results with similar ones referring to the same reaction in vacuo (J. Mol. Struct., *Theochem*, 87 (1982) 181). Attention is paid to alternative mechanisms involving ionic dissociation of the reactant. (36 refs.)

77868 Molecular topology and chemical reactivity: interaction of a chemical bond with simple cubic, body centered cubic and face centered cubic alkali metal lattices. J.Pancir, R.Zahradnik (J. Heyrovsky Inst. of Phys. Chem. & Electrochem., Acad. of Sci., Prague, Czechoslovakia). *THEOCHEM (Netherlands)*, vol.11, no.1-2, p.23-35 (June 1983). The simplest version of a topological method is used to study the interaction between a chemical bond (parametrized as a hydrogen molecule) and metal crystals parametrized as sodium. Planes with Miller indices of (100), (110), (111), and (112) are considered for simple cubic (SC), body centered cubic (BCC) and face centered cubic (FCC) lattices. Throughout the calculation, all electronic repulsion integrals are neglected and uniform metal-metal bond strengths assumed. Interaction energies are calculated by the second order perturbation theory. All the planes of the SC and BCC lattices have uniform charge distribution because only even-membered rings are present. Of all the interactions studied, the bonding of one atom of the interacting diatomic molecule with two neighbouring metal atoms is preferred. If such a type of interaction is impossible for steric reasons, interaction of the chemical bond with two nearest non-neighbouring metal atoms is most advantageous. Interaction energies with SC and BCC lattices are smaller than those for isolated atoms but the opposite is true for the FCC lattice. Simple selection rules are suggested which control interaction between a chemical bond and the σ part of any metal cluster. (9 refs.)

77869 Catalytic effect on the selectivity of the Diels-Alder reaction. V.Branchadell, A.Oliva, J.Bertran (Dept. de Quimica Fisica, Univ. Autònoma de Barcelona, Barcelona, Spain). *Chem. Phys. Lett. (Netherlands)*, vol.97, no.4-5, p.378-80 (27 May 1983). Using the MINDO/3 method, variation of the potential barrier for the Diels-Alder reaction between 1-hydroxybutadiene and acrolein, catalyzed by BF_3 and NH_4^+ , has been studied. An interpretation of the experimental facts about the increase of regioselectivity and stereoselectivity for Diels-Alder reactions catalyzed by Lewis acids is given. (27 refs.)

77870 The evaluation of synthetic strategies for oligonucleotides of defined sequence. I. Computer programs in nucleic acid synthesis. S.Lombardi, H.Seidell, J.Hachmann (Oligonucleotides Section, Genex Corp., Rockville, MD, USA). *Comput. Programs Biomed. (Netherlands)*, vol.16, no.1-2, p.71-6 (Feb.-April 1983). Describes a computer program to aid in the evaluation of strategies for the synthesis of oligodeoxyribonucleotides of defined sequence. The program reduces the time required for the development of the most cost-effective strategy from several hours to a few minutes. The chemist supplies the program with the order of internucleotide bond formation, the final amount of material desired and the data giving anticipated reaction yields and molar ratios of reactants. The M_n and amount required for each intermediate in the proposed synthetic approach is then calculated. All of these data can be stored, edited or printed. By changing various input parameters (e.g. order of internucleotide bond formation, expected reaction yield), the chemist can utilize this program to analyze multiple synthetic approaches rapidly. The synthetic approach that will minimize the amounts of the expensive starting materials needed to complete the synthesis of the desired DNA can thus be quickly identified. (25 refs.)

77871 Mechanistic studies of oxene reactions with organic substrates: reaction paths on MINDO enthalpy surfaces—models for cytochrome P450 oxidations. A.T.Pudzianowski, G.H.Loew (Life Sci. Div., SRI Internat., Menlo Park, CA, USA). *Int. J. Quantum Chem. (USA)*, vol.23, no.4, p.1257-68 (April 1983). In a systematic study, the characteristics of triplet oxene models for alkane, alkene, chloroalkane, and aryl oxidations by the cytochrome P450s have been examined using the semiempirical molecular orbital method MNDO and the formalism of statistical mechanics. Specific model substrates chosen were: methane, ethylene, propene, carbon tetrachloride, chloroform, and toluene. It was found that transition state geometries and activation entropies were reliably predicted, but that an empirical factor was necessary to correct overestimation of activation enthalpies. It was determined that both hydroxylations and epoxidation initiated by a $O(^1P)$ atom are nonconcerted; and that oxidations of C-Cl bonds (halosylations) occur by a two-step mechanism similar to hydroxylation. It is shown that the radical mechanisms derived from these studies are consistent with a range of observed properties of cytochrome P450 reactions and provide reasonable explanations for secondary deuterium isotope effect and substituent effects in cytochrome P450 epoxidation of styrenes, suicide inactivation of a P450 enzyme by ethylene, and the characteristics of aerobic CCl_4 and $CHCl_3$ metabolism. A triplet oxene mechanism for the initial steps of aromatic epoxidation and hydroxylation is also discussed. (36 refs.)

77872 Sequential isomerism of activated complexes: interfering versus noninterfering intermediate. Z.Slanina (J. Heyrovsky Inst. of Phys. Chem. & Electrochem., Acad. of Sci., Prague, Czechoslovakia). *Int. J. Quantum Chem. (USA)*, vol.23, no.4, p.1553-61 (April 1983). A unimolecular process is considered that was treated experimentally as a concerted one; however, subsequent quantum-chemical analysis has proved that the process is realized via an intermediate (double sequential isomerism of activated complexes). The intermediate is supposed to contribute directly to values of the primary observed data (e.g., spectral absorbances). Within this approach of interfering intermediate any degree of this interference is allowed including the limit case of noninterfering intermediate serving as a reference standard. A technique a suggested enabling correct comparison of the quantum-chemical outputs with the experimental overall values for rate constants and activation enthalpy and entropy. The technique employs mere amount of information currently obtainable from quantum-chemical study of a rate process (i.e. representation of potential energy hypersurface by its stationary points and activated-complex theory). Properties of the derived formulae are illustrated with model examples. The results are important for meaningful comparison of experimental and theoretical data in the case of processes with sequential isomerism of activated complexes disclosed only theoretically. (28 refs.)

77873 Topological determinants in organic chemistry. P.G.Seybold (Dept. of Chem., Wright State Univ., Dayton, OH, USA). *Int. J. Quantum Chem. (USA)*, vol.23, no.4, p.1683 (April 1983). Summary form only given. It is well recognized that molecular topology determines or strongly influences many molecular properties, but a more precise description has remained elusive. A graph-theoretical technique is introduced to analyze topological features of conjugated and aromatic networks. An atomic structural index, related to the molecular Wiener index, can be used as a measure of the connectedness of an atom to other atoms of a network. Thus it is recognized that some positions are strongly connected, and others weakly connected, to the conjugated system. Substitutions or replacements as strongly connected positions have a greater effect on molecular properties than those at weakly connected positions. Two fundamental features of the carcinogenic activity of polycyclic aromatic hydrocarbons (PAHs) serve as illustrations. Using graph-theoretical analysis, it can be shown that the 'bay region' geometry, believed important for the carcinogenic activity of many PAHs, allows carbonium ion formation to occur at strongly connected positions, thereby yielding more stable carbonium ions. Furthermore, many features of the effects of substituents on carcinogenic activity can be understood on simple topological grounds. Applications to a variety of topics in organic chemistry are in progress. (no refs.)

77874 Solvent effects in organic chemistry studied by correlation analysis. N.B.Chapman (Dept. of Chem., Univ. of Hull, Hull, England). *Indian J. Phys. Part B*, vol.56B, no.6, p.9-14 (Dec. 1982). [received: May 1983] The author studies the effect of a change of solvent on the kinetics of organic reactions. He presents some recent work done by his own group by selecting a range of pure liquids as solvents to avoid 'solvent-sorting'. They make much use of the reactions between carboxylic acids (mainly aromatic) and diazodiphenylmethane (DDM) which are readily followed by visible spectroscopy. Moreover such reactions are facile with otherwise unreactive acids and the mechanism, which involves a rate-limiting proton transfer, is well-established. (10 refs.)

77875 Dynamics of $O(^1D_2)$ reactions with bifunctional substrates: alcohols and thiols. N.Goldstein, J.R.Wiesenfeld (Dept. of Chem., Cornell Univ., Ithaca, NY, USA). *J. Chem. Phys. (USA)*, vol.78, no.11, p.6725-31 (1 June 1983). The OH and OD product ratios and vibrational distributions following the reactions of $O(^1D_2)$ with isotopically labeled alcohols and several thiols were characterized using laser induced fluorescence. The primary site of $O(^1D_2)$ attack upon the alcohols is the O-H bond, attack upon the C-H bond also being observed. Both reactions occur via an insertion/elimination mechanism. Product vibrational distributions for each pathway are similar to those observed following reaction with the corresponding monofunctional substrate. (33 refs.)

77876 Determination of product population and alignment using laser-induced fluorescence. C.H.Greene (Dept. of Phys. & Astron., Louisiana State Univ., Baton Rouge, LA, USA), R.N.Zare. *J. Chem. Phys. (USA)*, vol.78, no.11, p.6741-53 (1 June 1983). For collision systems having axial symmetry, the anisotropy of the laser-induced fluorescence is given explicitly in terms of the zeroth, second, and fourth rank moments of the angular momentum distribution, which, respectively, are proportional to the population, the quadrupole alignment, and hexadecapole alignment of the product internal state under study. Expressions are presented for determining these three quantities from the dependence of the fluorescence intensity on the polarizations of the absorbed and detected photons. Results are presented for an arbitrary excitation-detection geometry which is then specialized to the commonly occurring cases where the direction of fluorescence detection is at right angles to the axis of cylindrical symmetry and the direction of the incoming light beam is either along the axis of cylindrical symmetry or at right angles to it and to the fluorescence detection direction. The approach of these expressions to the high- J limit is considered. The effect of nuclear spin on the fluorescence intensity is analyzed and the extent of depolarization is shown to be unimportant for large J . The use of

angular momentum recoupling algebra permits the geometrical and dynamical aspects of this problem to be completely disentangled. (23 refs.)

77877 On the reaction $\text{Mg} + \text{N}_2\text{O} \rightarrow \text{MgO} + \text{N}_2$. D.R.Yarkony (Dept. of Chem., Johns Hopkins Univ., Baltimore, MD, USA). *J. Chem. Phys. (USA)*, vol.78, no.11, p.6763-72 (1 June 1983). The lowest singlet ($^1A'$) and triplet ($^3A'$) potential energy surfaces of the reaction $\text{Mg} + \text{N}_2\text{O}(\Sigma^+)=\text{MgO} + \text{N}_2(\Sigma^+)$ are investigated using ab initio SCF, two configuration MCGSCF and CI wave functions. The reactivity of $\text{Mg}(^1S)$ and $\text{Mg}(^3P)$ is contrasted. These surfaces can be qualitatively partitioned into three contiguous, nonadjacent regions characterized by distinct values of an approximate reaction coordinate (ξ): a reactant region in which $\xi \approx \xi_1 \approx R(\text{Mg}-\text{O})$, a bending region in which $\xi \approx \xi_2 \approx \angle \text{NNO}$, and a product region in which $\xi \approx \xi_3 \approx (N-O)$. Evolution into region 3 requires Mg to N_2O charge transfer which facilitates, and is facilitated by, bending of N_2O . On the $^1A'$ surface which correlates with $\text{MgO}(^1\Pi)$, this process is largely downhill and involves an orbital reorganization in the N_2O moiety for $\xi \approx \xi_3$. A small barrier to vertical charge transfer is predicted at the CI level. On the $^3A'$ surface, which correlates with $\text{MgO}(^3\Sigma^+)$ approach is uphill for $\xi \approx \xi_1$. Possible explanations for the profound differences in the reactivity of calcium and magnesium with N_2O are suggested. (50 refs.)

77878 Vibrational excitation of the allene-fluorine reaction in cryogenic matrices: possible mode selectivity. A.K.Knudsen, G.C.Pimentel (Chem. Dept., Univ. of California, Berkeley, CA, USA). *J. Chem. Phys. (USA)*, vol.78, no.11, p.6780-92 (1 June 1983). The infrared induced reaction of allene (C_3H_4) and fluorine in N_2 , Ar, Kr, and Xe matrices at 12 K has been studied. The reaction is promoted by the selective vibrational excitation of $\text{C}_3\text{H}_4\text{F}_2$ reactive pairs and the course of the reaction followed by infrared spectroscopy. Four products are detected, consistent with the concerted addition of F_2 across the C-C double bond to form vibrationally excited cis- and gauche- $\text{CH}_2\text{CFCH}_2\text{F}$ which may then eliminate HF to yield either $\text{CH}\equiv\text{CH}_2\text{FHF}$ or $\text{CH}_2=\text{C}=\text{CHFHF}$ pairs. The relative abundance of each product depends markedly upon the matrix. Selective vibrational photoisomerization of $\text{CH}_2=\text{CFCH}_2\text{F}$ was used to distinguish and assign spectral features due to the cis- and gauche-rotamers as well as to provide evidence about the torsional barrier in the matrix. In a particular matrix, the allene-fluorine reaction product distribution is independent of the exciting frequency, with measurements at 1679, 1953, 1999, and 3076 cm^{-1} . However, the relative quantum yield at 3076 cm^{-1} is three orders of magnitude higher than observed at the lower frequencies. Furthermore, the quantum yields at 1680, 1953, and 1999 cm^{-1} show differences that implicate mode selectivity in the allene-fluorine reaction. The CH_2 rocking overtone $2\nu_9$ at 1999 cm^{-1} and perhaps as well the CH_2 bending overtone $2\nu_{10}$ at 1679 cm^{-1} show a higher reaction propensity than that of the asymmetric skeletal stretching vibration ν_6 at 1953 cm^{-1} . (31 refs.)

77879 Transient kinetics of chemical reactions with bounded diffusion perpendicular to the reaction coordinate: intermolecular processes with slow conformational changes. N.Agmon, J.J.Hopfield (Div. of Chem. & Biology, California Inst. of Technol., Pasadena, CA, USA). *J. Chem. Phys. (USA)*, vol.78, no.11, p.6947-59 (1 June 1983). Intramolecular reactions inside macromolecules (e.g., binding of ligands to iron inside heme proteins) may often be coupled to slow random fluctuations in the reaction center geometry. This motion is 'perpendicular' to the reaction coordinate. It can be described as bounded diffusion in the presence of a binding potential field and an intramolecular rate constant which depends on the perpendicular degree of freedom. The diffusion equation is solved under the appropriate reflective boundary conditions. The transient decay of the total population is multiexponential (power law) for small diffusivity, changing to monoexponential kinetics for large diffusivity. For large times or large diffusivity, direct integration is very tedious, but an eigenvalue expansion converges rapidly. It also allows the calculation of the 'average survival time' (an extension of the 'first passage time') a natural candidate for replacing the reciprocal rate constant in multiexponential kinetics. An example is given for electron transfer between two loosely bound sites in a macromolecule. The average survival time shows a non-Kramers dependence on diffusivity, of the found in the binding kinetics in heme proteins. (26 refs.)

77880 Comparison of chemical reactions in liquid lithium with those in liquid sodium. R.J.Pulham, P.Hubberstey (Chem. Dept., Univ. of Nottingham, Nottingham, England). *J. Nucl. Mater. (Netherlands)*, vol.115, no.2-3, p.239-50 (April 1983). A comparison is made of the chemical properties of liquid lithium and of liquid sodium which are relevant to the use of the liquid metals in fusion and fission reactors. The liquids dissolve both metals and non-metals: the solubility of transition metals is enhanced by the presence of dissolved non-metals, e.g. nitrogen and oxygen, and this is most obvious in the case of lithium contaminated with nitrogen where the enhanced solubility is accompanied by the existence of stable ternary nitrides, e.g. Li_3FeN_2 . The solubilities of selected non-metals, hydrogen, carbon, nitrogen and oxygen, in the liquid metals are compared, and the fate of salts with polyatomic anions, e.g. NaOH , Li_2CO_3 , is discussed. Chemical reactions are followed in the laboratory, often by pressure and electrical resistivity techniques, and more recently by electrochemical cells. The reactions can be divided arbitrarily into non-metal with non-metal, non-metal with dissolved metal, and non-metal with solid transition metal. (32 refs.)

77881 Ternary ion exchange. IV. Activity corrections for the solution phase. P.Fletcher, R.P.Townsend (Dept. of Chem., City Univ., London, England). *J. Chem. Soc. Faraday Trans. II (GB)*, vol.79, pt.3, p.419-32 (March 1983). For pt.III see ibid., vol.77, p.2077 (1981). A previously developed model for the evaluation of activity coefficient ratios in mixed dilute solution is employed with particular respect to ternary cation exchange in zeolites in the presence of up to three different coanions in solution. Potential errors arising from ignoring either completely or partially the non-ideality correction for the solution phase are evaluated and discussed. Exchanges involving counter-ions of the same valency, or involving ions of different valencies, are both considered. It is shown that when all the counter-ions have the same valency, the magnitude of the non-ideality correction is independent of the selectivity of the exchanger. When the valencies of the counter-ions are different it is essential to apply the mixed-salt activity correction for any accurate studies of ternary ion-exchange equilibria. (18 refs.)

77882 Proton phototransfer and nonradiative deactivation in hydrogen-bonded complexes of 2-anthrol. L.M.Rubekov, B.M.Uzhinov. *J. Appl. Spectrosc. (USA)*, vol.36, no.5, p.562-5 (May 1982). Translation of: *Zh. Prikl. Spektrosk. (USSR)*, vol.36, no.5, p.792-6 (May 1982). [received: Feb. 1983]. Studies the energy decay processes of electron excitation concurrent with intra-complex transfer of a proton in excited complexes of 2-anthrol, as well as energy decay in which ion pairs are formed. (9 refs.)

77883 Chemical transport of MnS and MnSe using HCl as a transporting agent. A.Pajczkowska (Inst. of Phys., Polish Acad. of Sci., Warsaw, Poland). *Mater. Res. Bull. (USA)*, vol.18, no.4, p.397-403 (April 1983). The preparation of MnS and MnSe single crystals by chemical transport in a closed system with HCl as a transporting agent has been studied. The reaction of NH_4Cl and Cl_2 serves as a source of dry HCl. The results of thermodynamic calculations and experiments are discussed. MnS crystals grow with two types of platelet shapes in the low temperature region, and as octahedra at temperatures above 1100 K . MnSe crystals grow only in the octahedral form. The transport rate for MnS is higher than that for MnSe for ΔT greater than 50 K . Single crystals of MnS and MnSe in the form of octahedra with a maximum edge length of 4 mm were obtained. (9 refs.)

77884 Diffusional-drift-influenced chemical reactions at all gas densities. M.R.Flannery (School of Phys., Georgia Inst. of Technol., Atlanta, GA, USA). *Phys. Rev. Lett. (USA)*, vol.50, no.21, p.1656-9 (23 May 1983). In chemical reactions between species A and B, which interact within a background gas at high density N via a non-Coulomb attraction, it is shown that the key sequence of physical mechanisms for transport is diffusion at asymptotic (A-B) separations R , diffusional drift at intermediate R , and pure diffusion at the reaction sink. Reduction in gas density N causes the onset at the sink of pure inward drift. For pure Coulomb species in a gas, the corresponding sequence is asymptotic drift, diffusional drift, and pure diffusion at high N , and diffusional drift at lower N . (7 refs.)

77885 Potential surfaces for simple rearrangements. J.A.Pople (Dept. of Chem., Carnegie-Mellon Univ., Pittsburgh, PA, USA). *Pure & Appl. Chem. (GB)*, vol.55, no.2, p.343-6 (Feb. 1983). (International Symposium on Theoretical Organic Chemistry, Dubrovnik, Croatia, Yugoslavia, 30 Aug.-3 Sept. 1982). Quantum mechanical methods for the location and characterization of rearrangement transition structures are reviewed. Activation barriers are shown to be sensitive to the inclusion of polarization basis functions and electron correlation. Applications to vinylidene-acetylene rearrangements are described. The parent species, H_2CC , rearranges to HCCH without a significant activation barrier. However, significant barriers are found for certain substituted vinylidenes. (14 refs.)

82.35 POLYMER REACTIONS AND POLYMERIZATION

77886 Gelation in finite polycondensation systems. J.F.Yan (Weyerhaeuser Technol. Center, Weyerhaeuser Co., Tacoma, WA, USA). *J. Chem. Phys. (USA)*, vol.78, no.11, p.6893-6 (1 June 1983). Flory's theory of gelation is modified with the consideration of the conservation of both polymers and monomers. This result is an implicitly renormalized truncated weight distribution applicable to the entire system. Weight-average degree of polymerization is obtained by using the cascade theory with a finite number of generations. The dispersity of the weight distribution reaches a maximum at the gel point. In the post-gel region, a new relation for calculating the extinction probability is obtained. Results on weight-average DP and the gel fraction are in excellent agreement with those obtained by Donoghue and Gibbs (1979) and Ziff and Stell (1980). (8 refs.)

77887 Thermal isomerization and degradation of polyacetylene. P.Bernier (Groupe de Dynamique des Phases Condensées, Montpellier, France), S.Lefrant, M.Rolland, M.Aldissi, M.Galtier, A.Montaner, C.Linaya, F.Schue. *J. Electron. Mater. (USA)*, vol.12, no.2, p.289-322 (March 1983). Presents an experimental study of the isomerization from cis to trans (CH), induced by a thermal treatment of the film. Infrared, Raman, EPR and

NMR spectroscopies have been used, in addition to DC conductivity measurements, in order to characterize the kinetics of the isomerization process. All the spectroscopic methods show that the isomerization is thermally activated with an activation energy of ~18 kcal/mole. It is also shown that degradation processes are also involved and an activation energy close to 30 kcal/mole is derived from EPR data. Optimal conditions to perform a thermal isomerization of cis-(CH)_x, with respect to the extent of conjugation, are suggested. (28 refs.)

77888 Biceritricity in the polymerization of chains and rings. J.C.Wheeler, R.G.Petschek (Chem. Dept., Univ. of California, San Diego, La Jolla, CA, USA), P.Pleuty.

Phys. Rev. Lett. (USA), vol.50, no.21, p.1633-6 (23 May 1983). The equilibrium polymerization of chains and rings can be viewed as a biceritric point in a suitably augmented parameter space. The polymerization of chains in equilibrium with rings is described by the cross-over exponent, ϕ , for quadratic anisotropy in the $O(n)$ vector model with $n \rightarrow 1$. While the total mass fraction of polymerized material is described by the Ising exponent α , the mass fraction of chains separately (and therefore also of rings) is described by the exponent $\alpha_c = \phi - 1 + \alpha$. (16 refs.)

Statistical theory of the degree of polymerizationSee Entry 74392

82.40 CHEMICAL KINETICS AND REACTIONS: SPECIAL REGIMES

77889 A nonlinear problem arising from combustion theory: Linan's problem. S.P.Hastings (Dept. of Math., State Univ. of New York, Buffalo, NY, USA), A.B.Poore.

SIAM J. Math. Anal. (USA), vol.14, no.3, p.425-30 (May 1983). The differential equation $y'' = y \exp(\alpha x - y)$, $\lim_{x \rightarrow \infty} dy/dx = -\theta$ and $\lim_{x \rightarrow \infty} dy/dx = 0$ for $\theta > 0$ governs the thin reaction diffusion zone in many diverse problem in combustion theory. This problem with $\theta = 1$ is known as Linan's problem and continues to arise through the use of large activation energy asymptotics in the study of various combustion phenomena. The main issues for this problem are those of existence and uniqueness which are established for each positive α and θ . (11 refs.)

77890 Instabilities, pattern formation, and turbulence in flames. G.I.Sivashinsky (Dept. of Math., Univ. of California, Berkeley, CA, USA). In book: *Annual review of fluid mechanics. Vol.15*, M.Van Dyke, J.V.Wehausen, J.L.Lumley [Ed.], p.179-99. Palo Alto, CA, USA: Annual Reviews (1983), 534 pp. [0 8243 0715 1]

Considerable progress has recently been achieved in the understanding of the nature and character of spontaneous instabilities in premixed flames. The paper is devoted to the latest theoretical results in this area, which have disclosed a deep affinity between flames and other nonequilibrium physical systems capable of generating regular and intrinsically chaotic structures. 82.40T Chemiluminescence and chemical laser kinetics
(see also 42.55K Chemical lasers, 78.60P Chemiluminescence)

77891 Singlet molecular oxygen pumping of IF $B^2\Pi(O^+)$. P.D.Whitefield, R.F.Shea, S.J.Davis (New Laser Concepts Branch, Air Force Weapons Lab., Kirtland AFB, NM, USA).

J. Chem. Phys. (USA), vol.78, no.11, p.6793-801 (1 June 1983). Chemiluminescence from the reactions: $I_2 + F_2$; $I_2 + F_2 + O_2(^1\Delta)$; and $I_2 + F + O_2(^1\Delta)$ has been studied. All three reactions produced emission from the $B^2\Pi(O^+) \rightarrow X^1\Sigma^+$ system of IF. The two reactions utilizing $O_2(^1\Delta)$ produced much higher chemiluminescent intensities than did the $I_2 + F_2$ reaction. The photon yield of the $I_2 + F + O_2(^1\Delta)$ reaction was measured to be 0.3%. Rotational and vibrational temperatures in IF(B) were determined. Rotational temperatures were approximately 300K while nonthermal vibrational distributions were observed. Possible mechanisms of IF(B) production are discussed. (30 refs.)

82.45 ELECTROCHEMISTRY AND ELECTROPHORESIS

(see also 66.10 Ionic conduction in liquids; for electro-osmosis, see 82.65)

77892 On the processes responsible for the degradation of the aluminium-lithium electrode used as anode material in lithium aprotic electrolyte batteries. M.Garreau, J.Thevenin, M.Fekir (CNRS Phys. des Liquides et Electrochimie, Paris, France).

J. Power Sources (Switzerland), vol.9, no.3-4, p.235-8 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). A study has been carried out of the different processes, chemical corrosion, solid state diffusion and mechanical disintegration, affecting aluminium-lithium electrodes formed either by an electrochemical or a pyrometallurgical process. Cycling operations present similar limitations with aprotic electrolytes using dioxolane and propylene carbonate as solvents, and $LiClO_4$ and $LiAsF_6$ as solutes. Preliminary tests conducted with compressed LiAl powder electrodes show the existence of other processes responsible for the degradation of these electrodes during cycling. (4 refs.)

77893 Mechanistic studies of oxide electrodes reversibly incorporating Li^+ ions. G.Pistoia (Centro di Studio per la Electrochimica e la Chimica Fisica, CNR, Rome, Italy).

J. Power Sources (Switzerland), vol.9, no.3-4, p.307-20 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). Transition metal oxides capable of reversibly incorporating Li^+ ions are examined with particular emphasis on their structural features. The thermodynamic, kinetic, and electrochemical aspects of the insertion processes are also discussed. (47 refs.)

77894 Introduction to the scaling properties in electrochemistry: from the 'TEISI' model to the lithium fractal ordering in $Li_0.5FeS_2$ layered structure. A.Le Mehaute, A.Dugast (Lab. de Marcoussis, Centre de Recherches de la CGE, Marcoussis, France).

J. Power Sources (Switzerland), vol.9, no.3-4, p.359-64 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). Attention is drawn to the generalisation to the fractal geometry of the relations which control the interfacial energy and mass exchange in the linear approximation. From this kinetic analysis the solid state motion of lithium in $Li_0.5FeS_2$ is shown to be related to the fractal ordering of this ion in the lattice. Scaling phase transitions are pointed out. (19 refs.)

77895 A reversible graphite-lithium negative electrode for electrochemical generators. R.Yazami, P.Touzain (Lab. d'Adsorption et Reaction de Gaz sur Solides, Domaine Univ., Saint Martin d'Heres, France).

J. Power Sources (Switzerland), vol.9, no.3-4, p.365-71 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). Lithium intercalation compounds in graphite have been obtained by electrochemical methods using a solid organic electrolyte (polyethylene oxide with lithium perchlorate). Intermittent electrochemical techniques have enabled the kinetic (diffusion coefficient) and thermodynamic (enthalpy) values to be calculated. Some secondary battery cycling tests using lithium-graphite as a negative electrode are reported. (10 refs.)

77896 Oxidized rare earth-iron compounds in photoassisted electrolysis of water. A.Shamsi, W.E.Wallace (Dept. of Chem., Univ. of Pittsburgh, Pittsburgh, PA, USA).

Mater. Res. Bull. (USA), vol.18, no.4, p.389-95 (April 1983). Anodes for use in a photoelectrolysis cell can be prepared by heating rare earth (R) iron compounds (RF_2 , RF_3 , R_2Fe_{17} and R_6Fe_{23}) in air using the flame of a Fisher burner. For comparison, iron oxide and titanium oxide were also prepared by heating iron and titanium metal in air. The current-voltage (I-V) properties of these materials were measured in an aqueous solution of 1 M NaOH. The flatband potentials (V_{fb}) were determined with respect to a fixed potential (SCE) by extrapolating the I-V curves to zero current. Anodic photocurrents were generated by light with energy exceeding the band gap of the photoanode material. Photoelectrolysis of water occurred, as evidenced by the evolution of oxygen from the $RFeO_4$ electrodes and hydrogen from the Pt electrode. Most of these electrodes were found to be stable under experimental conditions. (17 refs.)

77897 A conductance equation for binary liquid systems consisting of an electrolyte component and an indifferent solvent. Yu.Ya.Fialkov, N.I.Kulinich, V.L.Chumak (Kiev Polytech. Inst., Kiev, Ukrainian SSR). *Sov. Electrochem. (USA)*, vol.18, no.8, p.910-12 (Aug. 1982). Translation of: *Elektrokhimiya (USSR)*, vol.18, no.8, p.1024-7 (Aug. 1982). [received: May 1983]

A nonempirical conductance equation for binary liquid systems consisting of an electrolyte component and an indifferent solvent has been derived and analyzed; it links specific conductance to the electrolyte's viscosity, dielectric permittivity, and concentration. (8 refs.)

82.50 PHOTOCHEMISTRY AND RADIATION CHEMISTRY

(see also 33.50 Fluorescence, phosphorescence; radiationless transitions)

77898 A study in real and reciprocal space of the electron-beam-induced decomposition of sodium aluminum hydride single crystals. P.J.Herley (Dept. of Materials Sci. & Engng., State Univ. of New York, Stony Brook, NY, USA), W.Jones.

Mater. Lett. (Netherlands), vol.1, no.5-6, p.131-6 (April 1983). Decomposition induced by the electron beam has been studied using transmission electron microscopy in sodium aluminum hydride, NaAlH_4 , single crystals. Results show rapid formation of small diffuse nuclei. These nuclei do not increase in size appreciably but grow in number as the reaction proceeds. No evidence for cracking was observed at the hydride/product interface: the final product is a finely-divided aggregate of metallic particles. (6 refs.)

77899 The mechanism of the photochemical oxidation of water to oxygen with silver chloride colloids. K.Chandrasekaran, J.K.Thomas (Dept. of Chem., Univ. of Notre Dame, Notre Dame, IN, USA).

Chem. Phys. Lett. (Netherlands), vol.97, no.4-5, p.357-60 (27 May 1983). Photoexcitation of silver chloride colloids in the presence of excess silver ions leads to the decomposition of water. Hydroxyl radicals were found to be intermediates in the decomposition process. Irradiation leads to hydroxyl radicals, which recombine to give hydrogen peroxide, on the colloidal particle surface. Subsequent decomposition of H_2O_2 to give O_2 is catalyzed by silver ions. Addition of alcohols such as methanol and isopropanol reduce the oxygen yield, as they react with OH radicals and reduce the H_2O_2 yield. (10 refs.)

77900 Photoreduction of carbon dioxide to formic acid, formaldehyde, methanol, acetaldehyde and ethanol using aqueous suspensions of strontium titanate with transition metal additives. M.Ulman (Isotope Dept., Weizmann Inst. of Sci., Rehovot, Israel), A.H.A.Tinnemans, A.Mackor, B.Aurian-Blajeni, M.Halmann.

Int. J. Sol. Energy (Switzerland), vol.1, no.3, p.213-22 (1982). The photoassisted reduction of aqueous carbon dioxide was carried out in the presence of suspensions of powdered strontium titanate, surface treated with various transition metal oxide additives, using either high-pressure mercury lamps or sunlight as the energy source. The organic products observed included formic acid, formaldehyde, methanol, acetaldehyde and ethanol. (10 refs.)

77901 Connecting a chemical fast reactor to an AIM 65 microcomputer. G.R.Heal (Dept. of Chem. & Appl. Chem., Univ. of Salford, Salford, England).

Lab. Microcomput. (GB), vol.1, no.2, p.14-26 (Summer 1982). Describes how to record data from a flash photolysis unit on Rockwell AIM 65 microcomputer, via an analogue-digital converter (ADC). Details are given of how to wire the ADC and of machine code subroutines that set up the interface and run the ADC. The assembly program and the main control program (the latter in BASIC) are listed. (3 refs.)

77902 Solute-solvent exciplex versus twisted intramolecular charge-transfer state in anomalous fluorescence of 4-NN-dimethylaminobenzonitrile. R.J.Visser, C.A.G.O.Varma, J.Konijnenberg, P.Bergwerf (Dept. of Chem., State Univ., Leyden, Netherlands).

J. Chem. Soc. Faraday Trans. II (GB), vol.79, pt.3, p.347-67 (March 1983). The authors pay attention to four topics concerning the effects of solute-solvent interactions on the behaviour of electronically excited 4-NN-dimethylaminobenzonitrile, namely the influence of solvent deuteration on anomalous fluorescence yield, the Stokes shift of the fluorescence in a polar glassy solution, photoinduced electrical conductivity and a quantum chemical analysis of the implications of the exciplex model. (27 refs.)

77903 Photophysics of derivatives of all-trans-1,6-diphenyl-1,3,5-hexatriene (DPH). I. Model involving fluorescence from S_2 and S_1 excited states. P.C.Alford, T.F.Palmer (Chem. Dept., Univ. of Nottingham, Nottingham, England).

J. Chem. Soc. Faraday Trans. II (GB), vol.79, pt.3, p.433-47 (March 1983). Absorption, fluorescence excitation and emission spectra have been measured for several derivatives of all-trans-1,6-diphenyl-1,3,5-hexatriene (DPH) in several non-polar solvents over a range of temperatures. Emission is shown to occur from the low-lying $^1A_g^*$ state (S_1) and the $^1B_u^*$ state (S_2) which is at slightly higher energy. A model is proposed in which thermal repopulation of S_2 from S_1 proceeds at a rate which is comparable to radiative and non-radiative decay from S_1 . (27 refs.)

77904 Hydrogen production with visible light by using dye-sensitized TiO_2 powder. K.Hashimoto, T.Kawai, T.Sakata (Inst. for Molecular Sci., Okazaki, Japan).

Nouv. J. Chim. (France), vol.7, no.4, p.249-53 (April 1983). Hydrogen was produced from water by exciting various organic dyes on TiO_2 or Pt/TiO_2 with visible light in the presence of a reducing agent. The quantum efficiency of hydrogen production was estimated to be in the order of 10^{-1} for $\text{Ru}(\text{bipy})_2^{2+}$ with EDTA as the reducing agent. It is postulated that hydrogen is produced by the reduction of water through a dye-sensitized process. (29 refs.)

77905 Direct observation of the local-field-enhanced surface photochemical reactions. C.J.Chen, R.M.Osgood (Dept. of Electrical Engng., Columbia Univ., New York, NY, USA).

Phys. Rev. Lett. (USA), vol.50, no.21, p.1705-8 (23 May 1983). The enhancement of photochemical reactions on surface-supported metallic particles is reported. The result is obtained by UV photodissociation of organometallic molecules adsorbed on the supporting surface. Transmission electron-microscope micrographs of the resulting photodeposited film reveal enhanced deposition on and near the metal particles, and a clear interference pattern resulting from the mixing of the incident and reradiated light. The importance of the particle plasma resonance is described. (10 refs.)

77906 Formation of metal images by a new peel-apart system. S.Honma, E.Inoue (Imaging Sci. & Engng. Lab., Tokyo Inst. of Technol., Yokohama, Japan).

Photogr. Sci. & Eng. (USA), vol.27, no.2, p.47-50 (March-April 1983). The imaging photosensor is made of a photosensitive polymer layer, comprising a polymer and a photosensitive material such as a diazo compound, which is coated on a metal layer deposited over a base film, and a cover film is then laminated on the photosensitive layer. After imagewise exposure through the cover film, peeling off the cover film from the base followed by heating at 50 to 100°C for a few minutes forms metal images on these films. The photographic properties depend both on the polymers and photosensitive materials which constitute the photosensitive layer. For example, a positive metal image of the original is formed on the base film by the use of polyvinyl chloride (PVC) and 2,6-di-(4'-azidobenzal)-4-methylcyclohexane, whereas a negative

one is obtained by the use of 2,5-dibutoxy-4-morpholino-benzediazonium tetrafluoroborate as the photosensitive material. This imaging system gives a high contrast image ($\gamma > 10$), with a resolving power of 25 lps/mm. The total range of the image can be controlled from high to low gamma depending on the concentration of the photosensitive materials or variation of heating periods. (10 refs.)

77907 Gelatin-substituted cyanine dyes as spectral sensitizers for silver halide emulsions. R.Steiger (CIBA-Geigy Photochem. Ltd., Fribourg, Switzerland), J.F.Reber.

Photogr. Sci. & Eng. (USA), vol.27, no.2, p.59-65 (March-April 1983). Cyanine dyes which react with gelatin without significant cross-linking of the gelatin have been synthesized. Their reaction product, cyanine dyes chemically bonded to gelatin (gelatin-substituted cyanines), can be used to spectrally sensitize silver halide emulsion crystals. Some physical-chemical properties of gelatin-substituted cyanines in solution and adsorbed to silver halides are described. It is shown that only a small fraction of all bonded dye molecules present in the adsorbed gelatin layer are able to approach the AgHal crystal surface closely enough to enable direct charge transfer between the excited dye and the silver halide. Since only this fraction of the cyanine molecules was shown to spectrally sensitize, the contribution of Forster energy transfer must be negligible with respect to electron transfer in photographic emulsions, in agreement with previous experiments on evaporated AgHal layers. By using a gelatin-substituted cyanine as an energy donor and an appropriate cyanine acceptor directly adsorbed at the grain surface, concerted energy-electron transfer may occur. (11 refs.)

77908 Kinetics of silver cluster formation and trapped hole neutralization in silver halide emulsion grains digested with cadmium salts. C.Rippon, B.Levy (Polaroid Corp., Cambridge, MA, USA).

Photogr. Sci. & Eng. (USA), vol.27, no.2, p.65-74 (March-April 1983). Digestion of a monodisperse octahedral AgBr emulsion in the presence of CdCl_2 lowers the ionic conductivity of the emulsion grains, reduces the rate of photocharge decay, and increases the photographic sensitivity. $\text{Cd}(\text{NO}_3)_2$ digestion, KCl digestion and pAg adjustments with AgNO_3 and KBr yield much smaller changes in the parameters measured than are obtained with CdCl_2 digestion. The kinetics of photocharge decay are described by concurrent first- and second-order rate processes. CdCl_2 digestion reduces the rate of the first-order decay to a much greater extent than the second order decay. This corresponds to a shift of the order of the major reaction leading to silver cluster formation from first order to second order. Similarly, the photogenerated silver ion vacancy adjacent to a trapped hole is shown to be responsible for neutralization of the trapped photohole. The introduction of Cd^{2+} may promote the increase in photographic sensitivity for a number of reasons. The shift of the mechanism for silver cluster formation from first-order kinetics to second-order is considered to be an important factor contributing to the improved photographic response. The simultaneous increase in lifetime of the photocharge decay process allows time for an enhancement of the concentration of interstitial silver ions at fewer centers within a grain, thereby increasing the efficiency of photographic development. The combined effect of these processes is frequently an increase in photographic speed, fog stability, and improved high-intensity reciprocity characteristics. (42 refs.)

77909 A study of properties of clusters of photographic interest by means of a redox buffer solution. T.Tani (Res. Lab., Fuji Photo Film Co., Kanagawa, Japan).

Photogr. Sci. & Eng. (USA), vol.27, no.2, p.75-80 (March-April 1983). Properties of clusters of photographic interest were studied by oxidizing and reducing them in a redox buffer solution. The oxidation potential of latent images, formed in sulfur-plus-gold-sensitized emulsions was much more positive than those of latent images in unsensitized, sulfur-sensitized, reduction-sensitized, and-iridium-sensitized emulsions. The oxidation potential of latent images became more negative as the degree of the speed increase by each chemical sensitization increased. The oxidation potential of fog centers with excessive sulfur sensitization was much more positive (by more than 0.6 eV) than that of fog centers with excessive reduction sensitization. Latent sub-images as revealed by gold-latensification were reduced to form development centers by a buffer solution with a relatively negative redox potential. On the other hand, the oxidation potential of sub-images was more positive than that of latent images. Based on the above-stated results, conclusions are made on the mechanism of photographic sensitivity. (16 refs.)

77910 Image formation processes in concentric shell emulsions. J.W.Mitchell (Dept. of Phys., Univ. of Virginia, Charlottesville, VA, USA).

Photogr. Sci. & Eng. (USA), vol.27, no.2, p.81-94 (March-April 1983). The relevant aspects of the concentration theory are applied to image formation processes in direct positive and reversal emulsions. The production of these predominantly internal image emulsions with the introduction of controlled levels of physical lattice imperfection and internal chemical structural imperfection is discussed. Image formation processes in direct positive emulsions with surface-fogged grains are analyzed with emphasis on the variables responsible for sensitivity and contrast. Image formation during exposure and reversal processing of unfogged concentric shell and core-shell emulsions is then considered. Finally, the concentric shell internal image systems with reversal processing are compared with the usual negative surface image systems. (191 refs.)

77911 A preliminary report on radical yield alternation in even and odd linear alkanes irradiated at 77K: ESR evidence. M.Fukaya, K.Toriyama, M.Iwasaki (Government Industrial Res. Inst., Nagoya, Japan), T.Ichikawa, N.Ohta.

Radiat. Phys. & Chem. (GB), vol.21, no.5, p.463-5 (1983). It has been found that the yields of trapped alkyl radicals in linear alkanes irradiated at 77K exhibit an alternation depending upon whether the carbon number is even or odd. The alternation becomes more prominent in a series of higher alkanes starting from $n\text{-C}_{11}\text{H}_{24}$ to $n\text{-C}_{19}\text{H}_{40}$, for which the crystal structures as well as the ESR spectral features are known to exhibit a regular alternation. The results suggest that the radiation chemical events are affected by the molecular packing, that is the crystal structures at the chain end and/or the interchain structures. (7 refs.)

- 77912 Chemical effects of nuclear transformations in mixed potassium hexahaloeno-metallates (IV), $K_2MX_6Y_{6-n}$. I. Chemical effects of the $^{81}Br(n,\gamma)^{82}Br$ nuclear process in mixed potassium hexabromochloro-osmates (IV), $K_2OsBr_4Cl_{2-n}$. H.Muller, P.Bekk (Inst. für Anorganische Chem., Univ. Freiburg, Freiburg, Germany). *Radiat. Eff. (GB)*, vol.64, no.1-4, p.183-8 (1982). [received: May 1983] (Proceedings of the First International Conference on 'Radiation Effects in Insulators', Arco, Largo di Garda, Italy, 1981). The chemical fate of ^{82}Br recoil atoms with a mean recoil energy of 100 eV from the nuclear reaction $^{81}Br(n,\gamma)^{82}Br$ has been investigated in mixed potassium hexabromochloro-osmates(IV). The experimental results can be explained by the following reaction paths: $12 \pm 3\%$ primary retention, $9 \pm 1\%$ free bromide yield, $61 \pm 3\%$ billiard ball reaction, and $16 \pm 5\%$ products resulting from large disorder. $2 \pm 2\%$ of the ^{82}Br appear as hydrolysis products with unknown origin. The experiments have shown that the fate of ^{82}Br recoil atoms is equal for impacts with Br and Cl atoms. (19 refs.)
- 77913 Temperature effects on positronium formation and inhibition: a contribution to the elucidation of early spur processes. IV. Methanol and ethanol solutions. J.Talamoni, J.Ch.Abbe, G.Duplatre, A.Haessler (Div. de Chimie et Phys. des Rayonnements, Univ. Louis Pasteur, Strasbourg, France). *Radiat. Phys. & Chem. (GB)*, vol.21, no.5, p.431-8 (1983). Temperature effects between 173 and 348K on the inhibition of positronium formation by NO_3^- and Cl^- in methanol and in ethanol solutions have been investigated. Whilst the inhibition promoted by NO_3^- , a total inhibitor, is temperature independent, this is not the case for Cl^- , a limited inhibitor. However, different effects are observed in the two solvents and the role of the solvation states of the e^- (and of the e^+) is discussed. (24 refs.)

82.65 SURFACE PROCESSES

- 77914 Model cluster study of the acid-base properties of zeolite catalysts. R.Vetrivel, B.Viswanathan (Dept. of Chem., Indian Inst. of Technol., Madras, India). *THEOCHEM (Netherlands)*, vol.11, no.1-2, p.187-92 (June 1983). The remarkable catalytic properties of aluminosilicates are usually associated with their surface acid-base properties. These properties depend on various factors such as the nature of the metal ion which neutralises the negative charge created by $[AlO_4]^-$ units, the extent of metal ions exchange, the electrostatic field produced by such ions and the number of oxygen vacancies present at the surface. Several attempts have been made to evaluate the acid-base properties of these systems by a number of experimental procedures using probe molecules and also to correlate them with the observed specific catalytic activity. The authors devise theoretical procedures for estimating acid-base properties of solid catalysts and rationalise the observed catalytic properties on the basis of these estimated acid-base properties. (11 refs.)
- 77915 Photoreactions on finely divided semiconductors. O.Peshev (Inst. of General & Inorganic Chem., Acad. of Sci., Sofia, Bulgaria). *Int. J. Quantum Chem. (USA)*, vol.23, no.4, p.1529-33 (April 1983). Photoreactions on finely divided semiconductors are discussed. Experimental results on photo-oxidation of CO, isobutane, and NH₃ over UV-irradiated n-TiO₂ (anatase) particles of different size are discussed. The possibility of using size-quantized films for spectroscopy of absorbates is also considered. (6 refs.)
- 77916 Adsorption-complex isomerism and quantum-chemical studies in heterogeneous catalysis. Z.Slanina (J. Heyrovsky Inst. of Phys. Chem. & Electrochem., Acad. of Sci., Prague, Czechoslovakia). *Int. J. Quantum Chem. (USA)*, vol.23, no.4, p.1563-70 (April 1983). The present quantum-chemical studies of the interaction of gases with solid surfaces indicate frequently the existence of several different structures of the model cluster complex with the adsorbed system. The usual approach to this adsorption-complex isomerism consists of selection of the potential energy-lowest member of the set of isomers. A weighting treatment is presented within which all the isomeric structures (or the part of them that is active in the respective experimental technique) can contribute to the values of observables. The treatment suggested requires information amount which corre-

sponds to the usual capabilities of today's numerical quantum chemistry, i.e. concept of localized adsorption is employed. In this way correct theoretical equivalents of experimental data can be obtained. Two types of the isomerism are considered, viz. site-caused isomerism and adsorbate-caused isomerism. It is shown that the treatment in the latter case can, under acceptable assumptions, be reduced to the recently described technique for the site-caused isomerism. An illustrative example is presented based on the literature data about the water-silica interaction. The results are important for correct comparison of theoretical and observed data in the field of heterogeneous catalysis and sorption. (17 refs.)

- 77917 Radiation damage enhancement of the penetration of water into silica glass. C.Burman, W.A.Lanford (Dept. of Phys., State Univ. of New York, Albany, NY, USA). *J. Appl. Phys. (USA)*, vol.54, no.5, p.2312-15 (May 1983). A dramatic increase in the rate of penetration of water into silica glass as a result of ion implantation with noble gas ions is reported. The damage caused by the implantation leads to the rapid uptake of water to a saturation concentration of hydrogen of approximately 10^{22} atoms/cm³. The effects of ion implant dose and ion mass are investigated. The results indicate that the mechanism responsible for this enhanced penetration is the creation of chemically reactive defects which greatly enhance the reaction between the water and the silica network. (10 refs.)
- 77918 The adsorption and dissociation of methyl isocyanide on Rh(111). S.Semancik, G.L.Haller, J.T.Yates Jr. (Surface Sci. Div., NBS, Washington, DC, USA). *J. Chem. Phys. (USA)*, vol.78, no.11, p.6970-81 (1 June 1983). The coordination chemistry of methyl isocyanide (CH₃NC), and CO are similar in a number of transition metal complexes, and it is therefore of interest to consider the surface chemistry of these molecules. The authors have used high resolution electron energy loss spectroscopy (EELS), temperature programmed desorption (TPD), and Auger electron spectroscopy (AES) to characterize the interaction of CH₃NC with Rh(111). At 120K, EELS measurements indicate that CH₃NC adsorbed nondissociatively as a bridged species. As the coverage is increased, vibrational loss features attributable to singly coordinated bonding occur, and multilayers of CH₃NC eventually develop. In contrast, CO bonds initially to Rh in atop sites, with a bridged form occurring only at higher coverages. Thermally induced changes in the adsorbed CH₃NC have also been monitored; TPD shows that H₂, HCN, and N₂ are liberated from the surface between 350 and 850K, and EELS have been used to follow the vibrational mode changes that accompany decomposition. Additional insight was provided by adsorbing CH₃NC onto surfaces preadsorbed with O₂ or CO, both of which produced some site blocking. Other interactional effects include CO and perhaps carbonate formation when CH₃NC reacts with oxygen, and rapid removal of the intensity of the EELS modes associated with CO when CH₃NC is adsorbed onto preadsorbed CO. Comparisons are made with previous results for CH₃NC adsorption on Ni(111), Ag(311), and alumina-supported Rh clusters. (23 refs.)
- 77919 D₂O product angular and translational energy distributions from the oxidation of deuterium on Pt(111). S.T.Ceyer, W.L.Guthrie, T.-H.Lin, G.A.Somorjai (Dept. of Chem., Univ. of California, Berkeley, CA, USA). *J. Chem. Phys. (USA)*, vol.78, no.11, p.6982-91 (1 June 1983). The angular and translational energy distributions of D₂O produced from the oxidation of deuterium on the (111) crystal face of platinum have been measured over the surface temperature range of 440-913K. Although the angular distributions are described by a cosine function, the translational energy distributions deviate from the corresponding Maxwell-Boltzmann distributions. At the normal angle, the D₂O mean translational energy $\langle E \rangle / 2k$ varies from 220 to 400K over the temperature range investigated. Two mechanisms for the production of translationally cold product molecules are discussed. (38 refs.)
- 77920 Changes in reflectivity and emissivity of oxide systems subjected to the influence of continuous CO₂ laser radiation. P.A.Skiba. *J. Appl. Spectrosc. (USA)*, vol.37, no.2, p.909-13 (Aug. 1982). Translation of: *Zh. Prikl. Spektrosk. (USSR)*, vol.37, no.2, p.242-7 (Aug. 1982). [received: April 1983] Investigations of the thermochemical processes which occur under the influence of laser radiation are of great interest for obtaining selective changes of the properties of surface layers of solids and, in particular, of oxide materials. The accumulation of reaction products (metal) during the reduction of oxides sharply increases the reflectivity of the material. At the same time the temperature of the surface layer and, accordingly, the reaction rate are reduced. Therefore, in order to optimize the energy consumption in the laser-induced reduction of oxide materials and in order to obtain the required degree of surface layer conversion, the time t_i of the thermochemical instability of the oxide must be determined, i.e., the time in which a strong correlation exists between overheating and absorption; similarly, the time t_m at which the metal phase in the irradiated zone develops must be determined. It is possible to determine t_i and t_m by establishing the relation between the degree to which a thin surface layer of an oxide sample is reduced and the reflectivity or emissivity of the sample. Samples (sheets with a size of $6 \times 10 \times 3$ mm) of copper oxide (CuO), iron oxide (Fe₂O₃), and nickel oxide (NiO) and samples of a M 400 NN nickel-zinc ferrite were employed. (8 refs.)
- 77921 The mechanism of the CO₂ formation on Pt(111) and polycrystalline surfaces at low temperatures. T.Matsushima (Res. Inst. for Catalysis, Hokkaido Univ., Sapporo, Japan). *Surf. Sci. (Netherlands)*, vol.127, no.3, p.403-23 (May 1983). The mechanism of the reaction of oxygen with CO on Pt(111) and polycrystalline surfaces was studied at low temperatures, with reactive thermal desorption and isotope tracer techniques. Two CO₂ formation processes were observed. The first is the interaction between CO and oxygen adatoms, which takes place below 200K. The second is the reaction of CO adatoms with oxygen adatoms. The desorption flux of the product CO₂ of both processes shows a very sharp angular distribution along the surface normal. (29 refs.)
- 77922 Studies on a palladium hydrogen window. N.Mitsuishi, T.Yuki, I.Ichihara. *Technol. Rep. Kyushu Univ. (Japan)*, vol.55, no.6, p.537-43 (Dec. 1982). In Japanese. [received: May 1983] Studies have been conducted on the permeation characteristics of hydrogen-inert gas mixtures through a palladium alloy tube wall as a hydrogen window. The palladium alloy tube used was Pd-20%Ag-5%Au, 1.44 mm ID and 100 mm in length. Permeabilities of hydrogen and deuterium were measured at 400°C under atmospheric pressure using H₂-Ar and D₂-Ar mixtures. The same permeation experiment was performed with an H₂-D₂-Ar mixture. The permeation data of the mixture agreed with the theoretical estimation for the H₂, D₂ and Ar mixture using the values of the permeability obtained by the H₂-Ar, and D₂-Ar experiments. The permeation rates of the hydrogen isotope mixtures in the hydrogen window may be estimated by the authors' equations. (9 refs.)

77923 Catalytic hydrogenation with amorphous and crystalline $\text{Pd}_{80}\text{Si}_{20}$. B.C.Giessen, S.S.Mahmoud, D.A.Forsyth, M.Hediger (Materials Sci. Div., Inst. of Chem. Analysis, Boston, MA, USA). *Rapidly Solidified Amorphous and Crystalline Alloys*. Proceedings of the Materials Research Society Annual Meeting, Boston, MA, USA, Nov. 1981 (New York, USA: North-Holland 1982), p.255-8.
Several metallic glasses in the form of ribbons were screened for activity as hydrogenation catalysts. $\text{Pd}_{80}\text{Si}_{20}$ and $(\text{Ni}_{10}\text{Fe}_{90})_{80}\text{B}_{20}$ showed activity in reducing cyclohexene. $\text{Pd}_{80}\text{Si}_{20}$ was further examined for differences between the glassy and crystalline phases in the selectivity shown during hydrogenation reactions of *n*-hexenes, phenylethyne, α -pinene, and cyclododecene. No significant differences were found for catalytic selectivity in regard to cis-trans isomerization, double bond migration, and stereochemistry of addition under the reaction conditions used. Minor differences were observed in hydrogen-deuterium exchange. (5 refs.)

77924 On the structure of random tissues or froths, and their evolution. N.Rivier (Blackett Lab., Imperial Coll., London, England).

Philos. Mag. B (GB), vol.47, no.5, p.L45-9 (May 1983).

Von Neumann's law (1952), governing the evolution of two-dimensional soap bubble froths is shown to be a direct consequence of the structural law of Lewis (1928), and both express mathematically the most probable filling of space. Von Neumann's and Lewis's laws can therefore be generalised to a considerable variety of froths, tissues, metallurgical aggregates, etc., in two and three dimensions. Moreover, a hitherto arbitrary parameter in Lewis's law measures ageing of the structure. (10 refs.)

77925 Dust concentration measurement probe using beta attenuation. S.E.Slezak, R.O.Buckley (Dept. of Mech. & Industrial Engng., Univ. of Illinois, Urbana, IL, USA).

Rev. Sci. Instrum. (USA), vol.54, no.5, p.618-25 (May 1983).

A small probe utilizing the attenuation of the beta emissions from promethium-147 has been constructed and calibrated for measuring the suspension concentration of dusts in the range of 0.1 to 2.0 kg/m³. The absorption of beta particles (negatively charged electrons) is related to the amount of matter through which the particles pass. The probe discussed here measures the beta absorption through a 5.1-cm path length at sample rates up to 20 samples per second. The small size of the probe (16 cm overall) allows real-time in situ local measurements of the suspension of a dust. The basic theory of operation and details of the probe operation are presented. Data from the probe for use in dust flammability experiments are also presented. (17 refs.)

82.80 CHEMICAL ANALYSIS AND RELATED PHYSICAL METHODS OF ANALYSIS

77926 RECLAS: resonant-enhanced CARS from C_2 produced by laser ablation of soot particles. D.A.Greenhalgh (Engng. Sci. Div., AERE, Harwell, England).

Appl. Opt. (USA), vol.22, no.8, p.1128-30 (15 April 1983).

Reports the use of both CARS and resonant-enhanced CARS for simultaneous soot particle detection and gas phase temperature measurement. The technique uses a standard broadband single-pulse CARS spectrometer to simultaneously detect soot particles and determine their surrounding gas temperature and composition. (21 refs.)

77927 Fiber-optic absorption/fluorescence probes for combustion measurements. G.Kychakoff, M.A.Kimball-Linne, R.K.Hanson (Dept. of Mech. Engng., Stanford Univ., Stanford, CT, USA).

Appl. Opt. (USA), vol.22, no.10, p.1426-8 (15 May 1983).

Describes the use of fiber-optic probes to measure the concentrations of chemical species in combustion gases. The authors have been interested primarily in measuring the concentrations of minor species, including radicals such as OH, CH, CN, C₂, CH₂, NO, NH, and NH₂, which often serve as important reaction intermediates in combustion processes. Experimental measurements of the concentrations of these radicals are helpful in the development of fundamental combustion and chemical kinetics models. The techniques proposed could also be applied to pollution monitoring, control of industrial processes, or the development and testing of full scale devices such as gas turbine combustors. (8 refs.)

77928 The study of Cr-Mn-Ni-Si-N (20, 10, 4, 3 wt.%) stainless steel by ESCA and AES. Yu Chih-chung (Shanghai Inst. of Testing Technol., Shanghai, China).

Chin. J. Sci. Instrum. (China), vol.4, no.1, p.49-56 (Feb. 1983). In Chinese.
The in-depth composition profile of Cr-Mn-Ni-Si-N (20, 10, 4, 3 wt.%) stainless steel was obtained by ESCA and AES with argon ion sputter etching, and the chemical states of Si, Mn, Ni, Cr, Fe, O, C of surface composition elements were described. Mn appeared in its oxide state in a great depth. The reduction of the density of valence electron for Cr of the surface layer and the double-peak of the Cr LMM Auger spectra were observed. The variation of the valence electron orbit of Cr led to the drop of the anti-oxidizing capability. The addition of Mo and Si would make the thickness of surface oxygen enriched layer smaller and that would lead to an increase of its anti-oxidizing capability. (12 refs.)

77929 Automatic identification of maxima in X-ray fluorescence spectrum. J.H.Jordanov (Higher Chem.-Tech. Inst., Sofia, Bulgaria), T.V.Tsanov, R.Stefanov, N.Jordanov.

C.R. Acad. Bulg. Sci. (Bulgaria), vol.36, no.3, p.349-52 (1983).

The process of automatic identification can be divided into three stages: 1) initial identification of the found maxima with X-ray lines of the different elements within the identification interval; 2) drawing up a list of the chemical symbols of the elements whose lines were found in the sample and juxtaposition to every chemical symbol of a certain sum of weights of its lines; and 3) evaluation of the presence of an element in the sample in accordance with the sum of weights of its X-ray lines. (5 refs.)

77930 X-ray attenuation coefficients of carbon in the energy range 5 to 20 keV. L.Gerward (Lab. of Appl. Phys. III, Tech. Univ. of Denmark, Lyngby, Denmark).

Acta Crystallogr. Sect. A (Denmark), vol.A39, pt.3, p.322-5 (1 May 1983).

Mass attenuation coefficients for pyrolytic graphite have been determined by an X-ray energy-dispersive method with a relative experimental error of about 0.5%. Results are given for the Fe, Co, Cu and Mo α_1 and α_2 lines. (28 refs.)

77931 A programmable tristate voltage scan generator. S.Birlasekaran, H.N.Venkoba Rao (Central Electrochem. Res. Inst., Karaikudi, India).

Indian J. Technol., vol.20, no.11, p.457-60 (Nov. 1982). [received: May 1983]

A low cost single triangle function generator circuit for selected voltage excursion in a ramp or triangle wave is described. Initial potential, final potential and peak of the triangular pulse can be programmed along with the slope rate. Apart from single triangle function, discrete multiple number of triangles and continuously repetitive triangular waves can also be obtained. By suitably programming one can get ramp, square and rectangular pulses. (6 refs.)

77932 Direct current and complex plane polarographic behaviour of copper(II)-EDTA complexes. P.Sridhar, R.S.Subrahmanya (Dept. of Inorganic & Phys. Chem., Indian Inst. of Sci., Bangalore, India).

Indian J. Chem. A, vol.21A, no.10, p.953-7 (Oct. 1982). [received: April 1983]

The DC and complex plane polarographic behaviour of copper-EDTA system has been studied under conditions where pure (CuY^{2-}) and mixed hydroxy (CuYOH^{3-}) complexes are present. The reduction process is quasi-reversible by DC polarography while complex plane polarography reveals the process to be pretty irreversible. The interpretation of the charge transfer resistance (R_θ) value is given on the basis of the theoretical θ versus $E-E_0$ and q versus $E-E_0$ curves. The value of β (anodic transfer coefficient) needed for these calculations is obtained from the DC polarogram. The rate constants have also been calculated. (9 refs.)

77933 Polarographic studies of cobalt (III) complexes with biguanide and substituted biguanides. B.Datta, K.Singh, D.Sen (Dept. of Chem., Indian Inst. of Technol., Kharagpur, India).

Indian J. Chem. A, vol.21A, no.10, p.958-60 (Oct. 1982). [received: April 1983]

The polarographic reduction of Co(III) chloride complexes with biguanide and substituted biguanides has been studied in aqueous 0.1 M KCl and 0.01% gelatin. The complexes are reduced in two steps (one-electron and two-electron respectively) at the d.m.e. The process is irreversible for all the complexes except for the simple biguanide complex. The $E_{1/2}$ values, overall rate constants and activation energies of the electrode processes etc., have been found to be related to the average Dq values of the complexes. Variation of these parameters with the size and nature of the substituent on the parent ligand has also been studied. (12 refs.)

77934 HPLCs 'artificial intelligence' gives quality separations. R.Lehrer (DuPont Co., Wilmington, DE, USA).

Ind. Res./Dev. (USA), vol.25, no.4, p.116-19 (April 1983).

The four-solvent system in HPLC lets the researcher determine optimum composition for the mobile phase for any given separation in only seven experiments. New software operates the system and 'learns' to improve quality and to speed HPLC analyses. (4 refs.)

77935 Designing an analytical microscopy laboratory. R.Kossowsky (Westinghouse R&D Center, Pittsburgh, PA, USA).

J. Met. (USA), vol.35, no.3, p.47-53 (March 1983).
Contemporary materials characterization requires sophisticated electron microscopes with chemical analysis capabilities. Such instrumentation has progressed rapidly over the past decade and continues to improve. The author discusses the considerations involved in the major updating of the materials characterization laboratory of a large international corporation with a wide range of materials characterization requirements. The general capabilities, merits, and limitations of the most important analytical instruments are described, and the trial specimens and procedures used to evaluate the final candidate instrumentation are discussed. (12 refs.)

77936 Atomic scale analysis with the atom probe. S.S.Brenner, M.K.Miller (US Steel Res. Lab., Monroeville, PA, USA).

J. Met. (USA), vol.35, no.3, p.54-63 (March 1983).
The atom probe is a unique instrument, quite distinct from the electron-optical instruments more commonly used in microanalytical studies. It is conceptually very simple and yet its microstructural and microchemical resolution are still unsurpassed, in that it can show and analyse individual atoms. Recent instrumental advances, especially in computer control of data collection and processing, have greatly increased the versatility of the atom probe as an analytical tool for material science. The instrument has been successfully applied to a broad range of studies including phase transformations and interface segregation. The authors discuss the basic concepts and general operating characteristics of the atom probe, and demonstrate its applications in precipitation strengthening of HSLA steels, segregation in irradiated material and heat-treated alloys, and phase transformations. (19 refs.)

77937 Electron trajectory-linked phenomena in thin foil X-ray microanalysis. I.P.Jones, A.W.Nicholls (Dept. of Metall. & Materials, Univ. of Birmingham, Birmingham, England).

J. Microsc. (GB), vol.130, pt.2, p.155-64 (May 1983). (MICRO 82: High Resolution Electron Microscopy, London, England, 12-16 July 1982).
The methods of calculating electron trajectories are reviewed. Approximate methods may be necessary because of computing time problems on small computers. The various situations in microanalysis where electron trajectories are important are discussed in turn. It appears that the single scattering theory of Goldstein et al. (1977) is useful for situations dominated by high scattering angle events whereas the Gaussian theory of Doig et al. (1981a) may be appropriate to multiple low angle scattering. This type of calculation might turn out to be unnecessary if coincident counting techniques are exploited. (23 refs.)

77938 Prospects for improvement in EDX microanalysis. P.J.Statham (Link Systems Ltd., High Wycombe, England).

J. Microsc. (GB), vol.130, pt.2, p.165-76 (May 1983). (MICRO 82: High Resolution Electron Microscopy, London, England, 12-16 July 1982).
There is still considerable room for improvement in the EDX (energy-dispersive X-ray) technique, particularly for the analysis of thin samples in transmission electron microscopes. Further research is required to characterize changes which are introduced during specimen preparation and a technique for mass thickness determination has to be established which is both accurate and convenient to implement. Since detector efficiency is difficult to predict at low energies, a suitable standard sample needs to be found which produces X-ray peaks suitable for establishing fixed points on the detector efficiency curve. With current technology, there are several instrumental improvements which can be realized, most of which centre around the use of time-variant pulse-processing circuitry and reduction of electronic noise. Problems of overload with high-voltage microscopes can be minimized, resolution improved and pile-up rejection made more effective so that higher data rates can be accommodated. With the beryllium vacuum window removed, detection of boron is possible provided the influence of electronic noise is minimized; but further investigation is still required into the physics of interactions in the first 100 nm layer of the detector. (28 refs.)

77939 Condenser aperture misalignment and solute profile asymmetries in STEM X-ray microanalysis. G.Cliff (Dept. of Metall., Univ. of Manchester Inst. of Sci. & Technol., Manchester, England).

J. Microsc. (GB), vol.130, pt.2, p.RP3-4 (May 1983). (MICRO 82: High Resolution Electron Microscopy, London, England, 12-16 July 1982).
Large condenser apertures, used to increase the incident beam current and hence the X-ray counting statistics in STEM X-ray microanalysis, can increase beam convergence angles to the point where the effect of spherical aberration in the probe-forming lens will dominate and the electron probe will exhibit extensive non-Gaussian tails. These can be shown to contain a significant fraction of the incident beam current (Cliff and Kenway, 1982). More-over misalignment of an aperture which is larger than that required to limit the analysis probe may produce an asymmetry in the shape of the tails surrounding the probe. A typical electron distribution asymmetry is shown by the densitometer trace from the major axis of a STEM probe. Condenser aperture misalignment may have only a limited effect on bright field STEM image quality but it can introduce significant asymmetries into solute profiles measured by X-ray microanalysis at phase boundaries. (2 refs.)

77940 Determination of trace aluminum and calcium impurities by intracavity spectroscopy. V.S.Burakov, V.N.Verenik, V.A.Malashonok, P.A.Naumenkov, S.V.Nechayev, R.A.Puko.

J. Appl. Spectrosc. (USA), vol.37, no.2, p.869-71 (Aug. 1982). Translation of: *Zh. Prikl. Spektrosk. (USSR)*, vol.37, no.2, p.197-200 (Aug. 1982). [received: April 1983]

The high sensitivity of intracavity spectroscopy enables one to use it efficiently to determine low concentrations of various elements. However, attainment of the maximum possible sensitivity of the method in each specific case requires the refinement of a series of steps in the analysis process: selection of the type of laser, atomizer, conditions for recording the spectral absorption lines, preparation of the samples for analysis, etc. The authors elucidate a set of these conditions for the case of determination of low concentrations of aluminum and calcium by atomic-absorption intracavity spectroscopy, and establish the maximum possibilities of the method. Monitoring of the trace content of selected elements is important in a number of technological processes of the semiconductor industry. (8 refs.)

77941 Fundamental parameter of the optimum excitation conditions in the analytical emission spectroscopy. The difference in ionization potential between the matrix and the analysis elements in the plasma. Chen Meifang (Inst. of Precious Metals, Ministry of Metall. Industry of PRC, Kunming, China).

Kexue Tongbao (Foreign Lang. Ed.) (China), vol.28, no.2, p.178-83 (Feb. 1983).

The DC carbon arc source is one of the fundamental sources used in analytical emission spectroscopy. Though during the past two decades many other new sources have been developed, the carbon arc source, due to its simplicity, suitability and sensitivity, is still being commonly used in numerous fields. By using this source in the analysis of various materials, the study of the dependence of spectral line intensity on the composition of the samples is a subject

in which all workers in analytical emission spectroscopy are interested. The aim of the present work is to study the dependence of spectral line intensity on different compositions of materials. (7 refs.)

77942 Microcolumns for more efficient LPC [liquid phase chromatography].

Mes. Regul. Autom. (France), vol.48, no.5, p.53-5 (5 April 1983). In French.
The Hewlett-Packard HP1090 low-dispersion chromatograph is described with an introductory review of microcolumn theory and estimates of savings from reduction of column diameter and length. The rate of flow is reduced fivefold, requiring a pump with 1 ml/min resolution. Chromatograms and graphs show the effects of column diameter, number of theoretical plates, and grain size, and contrast the detail obtainable from the same 100×2.1 mm microcolumn on the new product and on a standard apparatus. (no refs.) M.B.D.

77943 On the measurement of binding energies in liquid ESCA and the relation to electrochemical half-cell EMFs. H.Siegbahn, M.Lundholm, M.Arbram, S.Holmberg (Inst. of Phys., Uppsala Univ., Uppsala, Sweden).

Phys. Scr. (Sweden), vol.27, no.4, p.241-4 (April 1983).
The question of the reference level of the binding energy scale in liquid ESCA is discussed. The experimental conditions for liquid ESCA are equivalent to those for an electrochemical half-cell, which means that measured gas-liquid shifts can be related to differences in redox potentials. On this basis, liquid ESCA spectra can be referenced to the vacuum level by means of separately measured electrochemical data. (14 refs.)

77944 Determining distribution and concentration of certain elements with the aid of a charged-particle beam. I.G.Berzina, E.B.Gusev, A.V.Drushchits, V.S.Kulikasaus, A.F.Tulinov.

Sov. At. Energy (USA), vol.53, no.3, p.648-52 (Sept. 1982). Translation of: *At. Energ. (USSR)*, vol.53, no.3, p.178-81 (Sept. 1982). [received: May 1983]
The methods used in practice to determine the elements of which a substance is composed usually require destruction of the object to be examined and do not allow a selective simultaneous determination of both the distribution and the concentration of several elements. The authors use a method of elementary analysis which can be used for the selective simultaneous determination of the local concentrations of lithium, boron, oxygen, nitrogen, and fluorine with the aid of the (p,α) reaction and, besides that, with the (α, n) reaction for determining beryllium in micro- or macrosections of multicomponent objects. (4 refs.)

77945 X-ray fluorescence analysis for the detection of heavy metals in plant matter. H.Rethfeld (Agricultural Experimental & Res. Establ., Munster, Germany), L.Beitz.

Siemens Power Eng. (Germany), vol.5, no.2, p.55-7 (March-April 1983).
When plant matter is chemically monitored, a full analysis can be made with the X-ray fluorescence method in approximately 10 minutes. The specimens are easily prepared. For all plant matrices, evaluation of the measurements is carried out with only one calibration function per element. In the case of the heavy metals examined, i.e. chromium, manganese, iron, nickel, copper, zinc and lead, the limit of statistical proof was between 0.5 and 1 ppm. The analysis accuracy in the concentration range of 20 to 1000 ppm was approximately 2% relative. (6 refs.)

77946 Rapid chemical methods for identification and study of short-lived nuclides. G.Herrmann (Inst. für Kernchem., Univ. Mainz, Mainz, Germany), N.Trautmann.

In book: *Annual review of nuclear and particle science. Vol.32*, J.D.Jackson, H.E.Gove, R.F.Schwitters [Ed.], p.117-47. Palo Alto, CA, USA: Annual Reviews (1982), 595 pp. [0 8243 1532 4]

The authors outline recent trends in the design of rapid chemical separations, including some perspectives for future developments. They emphasize techniques that allow the isolation of individual elements from complex mixtures on a time scale of a few seconds with direct detection of their isotopes. They also include somewhat slower techniques in cases where very similar elements have to be separated. Since they wish to show how rapid separations can be performed technically, the article is organized according to the principal chemical step, not according to elements. They discuss first separations from and in aqueous solutions and then separations via gaseous phases. In solution chemistry one takes advantage of the broad experience accumulated over long times in radio-chemical separations; gas phase chemistry is less developed but very attractive for rapid work because of the short separation times involved. (100 refs.)

77947 Limitations of a single optical fibre fluorimeter system due to back-ground fluorescence. J.P.Gakin, A.J.King (Plessey Electronic Systems Res. Ltd., Havant, England).

First International Conference on Optical Fibre Sensors, London, England, 26-28 April 1983 (London, England: IEE 1983), p.195-9
Discusses the relative importance of fibre fluorescence in remote fibre fluorimetry in relation to experimental results and a likely mechanism has been found to explain the results obtained. (4 refs.)

86.00 ENERGY RESEARCH AND ENVIRONMENTAL SCIENCE

86.10 ENERGY RESOURCES AND THEIR UTILISATION

(inc. economic aspects; for nuclear engineering and nuclear power studies, see 28.00)

77948 Home energy use in nine OECD countries, 1960-1980. L.Schipper, A.Ketoff (Lawrence Berkeley Lab., Univ. of California, Berkeley, CA, USA). *Energy Policy (GB)*, vol.11, no.2, p.131-47 (June 1983). Government institutions and individuals have responded to fluctuations in energy supply and price with the implementation of policies and the initiation of conservation. While these activities have resulted in noticeable conservation of energy, primarily through behavioural actions, further savings could be achieved through the exchange of information regarding promising policies and technologies. Toward this end, data on residential sector energy use for nine OECD countries (Canada, Denmark, France, West Germany, Italy, Japan, Sweden, the UK and the USA) have been collected over the period 1960-1980 and have been analysed using both indicators of energy-use intensity and econometric methods. (21 refs.)

77949 Energy conservation in US buildings: solving the high potential/low adoption paradox from a behavioural perspective. A.Shama (Solar Energy Res. Inst., Golden, CO, USA). *Energy Policy (GB)*, vol.11, no.2, p.148-67 (June 1983). The engineering, economic and behavioural perspectives are discussed, and the importance of integration is emphasized. The framework for diffusion of innovations is shown to be useful in an understanding of how demand for energy conservation forms and spreads. Specific recommendations to speed the adoption of energy conservation are outlined. (23 refs.)

77950 UK energy policy—issues and priorities. J.Cheshire (Sci. Policy Res. Unit, Sussex Univ., Brighton, England). Colloquium on 'Resource Conservation for the Electrical Engineer', London, England, 19 April 1983 (London, England: IEE 1983), p.1/1-6. Compared with its major international competitors, the UK is well-endowed with three fossil fuels and nuclear construction and operating experience. However, complacency is to be avoided at all costs. This is because the lead times involved in RD&D and in conservation and fuel substitution investment are relatively long. The decade of the 1980s is unlikely to provide a fair reflection of the emergence of supply difficulties in the 1990s. Hence the need for carefully considered interventions by Government to underpin market forces. As far as the electricity sector is concerned, it is likely that a modest programme of thermal reactors will be launched but that the level of support for the breeder will be reduced in real terms and conducted more fully on an international, collaborative basis. Demand side electrical technologies, however, such as homeostatic controls and heat pumps, may well reach maturity and witness considerable increases in market penetration. (no refs.)

77951 Industrial energy usage. R.C.Bending (Cavendish Lab., Univ. of Cambridge, Cambridge, England). Colloquium on 'Resource Conservation for the Electrical Engineer', London, England, 19 April 1983 (London, England: IEE 1983), p.2/1-3. Discusses energy conservation and the role electrical engineers have to play in improving the efficiency of electrical energy in its familiar uses for motive power and lighting. Electricity may also have a growing role as a heat fuel in industry, and here the challenge to the electrical engineer is to ensure that the sophisticated techniques available are used, within the production process as a whole, in ways that are both cost-effective and energy-efficient. (no refs.)

86.10B Fossil and other fuels

77952 Alternative energy options. K.F.Bennett. *S. Afr. Mech. Eng. (S. Africa)*, vol.33, no.3, p.60-5 (March 1983). 'South Africa is going to be heavily reliant on coal as its prime energy source for the remainder of this century. None of the alternatives under investigation has the potential to alter this trend.' This in the conclusion the author arrived

at after examining all the alternative energy options available to South Africa. (28 refs.)

77953 Technical and economic analysis of the viability of heating equipment. J.M.Martins dos Santos. *Electr. Energ.-Electron. (Portugal)*, no.185, p.112-14 (March 1983). In Portuguese.

The author analyses the economic feasibility of heating equipment and establishes a procedure for decision making. (no refs.)

77954 Possibility for application of high CO_2 content gases to generate electric energy. G.Veres, S.Baliko (Budapesti Muzskai Egyetem, Budapest, Hungary). *Energ. & Atomtech. (Hungary)*, vol.36, no.1, p.30-7 (Jan. 1983). In Hungarian.

The authors discuss the possibility of using less combustible natural gases containing 40 to 80 vol. percent CO_2 occurring in large quantities in Hungary by means of the gas turbine conversion cycle. The influence of CO_2 upon the output and efficiency of the gas turbine are investigated, and various flow diagrams for increasing efficiency are analysed. (15 refs.)

77955 The potential supply of synthetic fuels from Alaskan hydroelectric power and coal. M.Steinberg, J.R.Powell (Dept. of Energy & Environment, Brookhaven Nat. Lab., Upton, NY, USA). *Int. J. Hydrogen Energy (GB)*, vol.8, no.5, p.355-62 (1983).

It is proposed to develop and utilize the large potential hydroelectric power resources in Alaska to produce hydrogen by the electrolytic decomposition of water and to combine the hydrogen with the large Alaskan coal reserves to produce synthetic liquid and gaseous fuels. It is estimated that in this manner, as much as 1.8 million bbls/day of gasoline or 6.2 billion SCF/day of substitute natural gas can be produced. The existing and projected Alaskan pipelines would provide the means of transporting the fuels to energy consuming load centers in the US. This development would move the US a considerable way towards energy independence as well as employing the natural resources in Alaska in an efficient manner. (10 refs.)

77956 Hydrogen for dual fuel engine operation. B.Haragopala Rao, K.N.Shrivastava, H.N.Bhakta (Dept. of Mech. Engng., Banaras Hindu Univ., Varanasi, India). *Int. J. Hydrogen Energy (GB)*, vol.8, no.5, p.381-4 (1983).

In the investigation, an attempt was made to burn hydrogen in compression ignition engines that were operated on a dual fuel principle. Hydrogen was supplied along with intake air in small proportions and ignition was initiated by injecting diesel fuel in the conventional manner. A single cylinder compression ignition engine was operated throughout its load range inducing small proportions of hydrogen in intake air. Such an operation resulted in an increase of thermal efficiency at full load, a reduction in exhaust temperature and an increase in maximum pressure. Nitrogen oxides in the exhaust were observed to increase though the hydrocarbon emissions reduced as expected. Closed vessel explosions were conducted to study the effect of adding a hydrocarbon to a hydrogen-air mixture on the flame propagation velocities. The effect of increasing the proportion of hydrogen in the hydrogen-hydrocarbon-air mixture was observed to increase the flame propagation velocity. (5 refs.)

77957 Safety's impact on an alternative energy source—coal. D.K.Denton (Coll. of Engng. & Technol., Southern Illinois Univ., Carbondale, IL, USA). *Occup. Health & Saf. (USA)*, vol.52, no.1, p.12-16 (Jan. 1983). [received: June 1983]

The ability to make underground mines a safe place to work will be a major concern to those seeking to use coal as an energy source. Increased production will stimulate a heightened concern for making mining a more effective energy resource. This effectiveness means that unless safe performance is achieved, the cost of poor safety, such as loss of lives and costly delays due to breakdowns and other failures, will greatly reduce productivity of underground mining operations. As such, coal companies and miners must be prepared to safely manage their operation before underground mining makes a significant effect on energy independence. (7 refs.)

77958 Modelling a peat power plant for development of new control strategies. K.Lehtomaki (Control Engng. Lab., Tampere Univ. of Technol., Tampere, Finland), U.Kortela.

Proceedings of the Fifth Power Plant Dynamics, Control and Testing Symposium, Knoxville, TN, USA, 21-23 March 1983 (Knoxville, TN, USA: Univ. Knoxville 1983), p.8/01-11 vol.1

Peat is a domestic fuel that today is used in several power plants in Finland. The inhomogeneity of peat causes extra difficulties in the operation and control of peat power plants compared with plants burning better fuels. The main purpose of the modelling work described is to build a model suitable for simulation and testing of different control strategies for peat power plants. The plant consists of many interconnected subprocesses. Because a fairly exact and covering model for the entire plant would include a great number of states and parameters, lots of restrictive assumptions have been made in the course of modelling. (5 refs.)

86.10D Wind energy

77959 Investigation and analysis concerning the atmospheric environment for wind turbine generator. H.Iwamura, T.Shimada. *Ishikawajima-Harima Eng. Rev. (Japan)*, vol.22, no.6, p.402-6 (Nov. 1982). In Japanese.

In 1981, a project for developing a 100 kW-class wind turbine generator was started, known as the 'Sunshine' national project. IHI started the research in 1979 to design a wind turbine generator. Wind observations have been conducted at Miyake Island since 1980. A summary of site measurement in the last two years are presented. (4 refs.)

77960 Wind power plant modelling and simulation. S.Bergman (Sydkraft AB, Malmo, Sweden), S.E.Mattsson.

Proceedings of the Fifth Power Plant Dynamics, Control and Testing Symposium, Knoxville, TN, USA, 21-23 March 1983 (Knoxville, TN, USA: Univ. Knoxville 1983), p.7/01-25 vol.1

A mathematical simulation model for a large horizontal axis wind turbine system is presented. Examples of performed simulations are also given. The model is intended for simulation of the synchronization of the wind turbine generator against the utility grid and the operation of the wind turbine system under different wind conditions and with different control algorithms. Particular attention has been given to the modularization. The model is divided into subsystems to make it easy to modify the model and adapt it to systems of similar type. The interactive simulation package SIMNON which allows

good structuring and programming in a high level language has been used. (12 refs.)

86.10K Solar energy

77961 Calculating internal radiation in greenhouses in the Evora region. A.M.Almeida E Silva, M.J.Petrolino Carvalho. *Electr. Eng.-Electron. (Portugal)*, no.185, p.122-6 (March 1983). In Portuguese.

Taking the hourly hemispherical radiation values in different inclined surfaces, the hourly beam radiation in a surface normal to the sun rays and the hourly diffuse radiation in a horizontal surface, given by Luis Aparicio da Mata of the INMG, the authors have calculated the hourly hemispherical radiation inside greenhouses, on the surface soil. The results obtained are one of the main components of the radiative balance and they are valid in any other greenhouse with different shapes. Although all the results cannot be presented here, the authors say that comparing the results of the different greenhouses, with other variables defining the radiative and heat balance, they can obtain the optimized model in a particular place with its climatic conditions. (4 refs.)

77962 Static concentrators theory for non-homogeneous extended sources. J.C.Minano, A.Luque (Univ. Politecnica de Madrid, Madrid, Spain). *Sol. Cells (Switzerland)*, vol.8, no.4, p.297-315 (May 1983).

Solar concentrators, in particular static solar concentrators, see the Sun as a sky-extended time-averaged non-homogeneous source. The rules for increasing the energy cast on the concentrator's collector are derived and figures of merit are proposed for concentrators working under these conditions. The preceding ideas are applied to several specific static concentrators illuminated by the time-averaged sky radiance of Madrid. The present paper generalizes from a previous paper on homogeneous extended sources but, in contrast with the conclusions which were reached for homogeneous sources, it was found that no upper limit exists for the power that can be cast in the collector. (8 refs.)

77963 Luminescent solar concentrators as bifacial captors. G.Lifante, F.Cusso, F.Meseguer, F.Jaque (Dept. de Optica y Estructura de la Materia, Univ. Autonoma de Madrid, Madrid, Spain). *Sol. Cells (Switzerland)*, vol.8, no.4, p.355-60 (May 1983).

The behaviour of luminescent solar concentrators (LSCs) as bifacial captors was considered. When these concentrators were coupled to a static diffusing reflector the overall efficiency was increased by 80%, regardless of the solar time. The effect of various geometries, LSC materials and diffusing surfaces was also studied. (9 refs.)

77964 Design and fabrication of the BDM southwest photovoltaic residence prototype. T.J.Lambarski, D.L.Forrester, C.G.Hoover (BDM Corp., Albuquerque, NM, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.205-10

The paper first presents an overview of the PV residence design including the residential energy features and the energy efficiency predictions, followed by a discussion of the PV array design with emphasis on the module bypass diode design, the series string selection, and array layout. Next the power conditioning design for the residence is presented. The paper concludes with a discussion of the experience gained from the prototype construction and operation. (4 refs.)

77965 Design and development of a point focus concentrated PV module operating above 100 suns. S.Olah, F.Ho, S.Khemthong (Appl. Solar Energy Corp., City of Industry, CA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.590-4

Describes the design, development fabrication and performance test of a highly efficient and cost effective concentrated photovoltaic module which can operate above 100 suns concentration and which can be mass produced and is reliable, with minimum maintenance. (no refs.)

77966 The design and development of a high concentration and high efficiency photovoltaic concentrator utilizing a curved Fresnel lens. A.L.Moffat, R.S.Scharlack (Thermo Electron Corp., Waltham, MA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.601-6

The design and development of an innovative photovoltaic concentrator which utilizes a low cost molded Fresnel lens is described. The lens design and fabrication are discussed, as well as the design of the collector module and tracking structure. A description of instrumentation developed to aid in the testing of lenses and solar cells is presented, and includes the test results. (no refs.)

77967 Design, processing, and assembly of large area concentrator cells and subassemblies. S.P.Tobin, M.J.Nowlan, G.A.Landis (Spire Corp., Patriots Park, Bedford, MA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.607-10

Describes the development of silicon concentrator cells for use in state-of-the-art linear focus Fresnel lens systems with average sunlight concentration of 30-50 suns. Primary goals were high cell efficiency and a simple, producible, low cost process. In the design phase, a collecting grid pattern optimized for the nonuniform intensity profile of the Fresnel lens was developed. A simple baseline cell process was defined. The most noticeable differences were the silicon resistivity (0.3 ohm-cm), texture etched surfaces to improve current collection, and the grid pattern. Initial cell results measured by Sandia were quite good, with efficiency exceeding 18% at 50 suns. Nine-cell strings interconnected and bonded to glass were delivered to the concentrator system manufacturer and passed all electrical and environmental tests. Several efficiency-enhancing options to the baseline process are also described. These include improved junction anneal schedules, oxide surface passivation, multi-layer antireflection coatings, and a planar process to reduce leakage currents. (5 refs.)

77968 Lithium-cupric sulfide cells. L.Werblan, J.Lesinski, A.Suzdorf, J.Lyzdorek, R.Drachal (Dept. of Chem., Univ. of Warsaw, Warsaw, Poland). *J. Power Sources (Switzerland)*, vol.9, no.3-4, p.409-16 (April-May 1983).

(International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). Results for the preparation and properties of cupric sulfide electrodes prepared by two different methods are given. Details concerning the chemical composition, the porosity, and the structure of the sulfide electrode are presented. Problems related to the selection of appropriate organic solvents and electrolyte solutions in order to determine those which would be compatible with the electrode materials (Li/CuS), and would also secure the best conditions for transport of charge and mass through the solution, are presented. The following solvents and their mixtures were tested: gamma-butyrolactone (gBL), tetrahydrofuran (THF), 1,2-dimethoxyethane (1,2-DME), 1,1-dimethoxyethane (1,1-DME), and two component mixtures of gBL with 1,2-DME and gBL with 1,1-DME. Transport phenomena—the electrical conductivity and viscosity of lithium perchlorate solutions in these solvents were measured. A laboratory technology for the construction of a Li/CuS cell has been developed. (12 refs.)

77969 Electrochemistry of a nonaqueous lithium/sulfur cell. H.Yamin, E.Peled (Dept. of Chem., Tel-Aviv Univ., Tel Aviv, Israel).

J. Power Sources (Switzerland), vol.9, no.3-4, p.281-7 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982).

The development and the electrochemistry of low-rate laboratory prototype Li/S button cells is described. The cell consists of a lithium anode, a porous catalytic current collector which is loaded with sulfur, and an organic solvent containing lithium polysulfide. The case of the cell was made from stainless steel and sealing was accomplished by the use of a combination of organic elastomer and cement (with no crimp). After 3 weeks storage at 60°C, the button cells lost only about 1 mg of weight. The lithium polysulfide reacts with the Li anode to form a passivating layer which acts as a solid electrolyte interphase (SEI). The EMF of the cells changes from 2.38 to 2.15 V depending on the composition of the solutions. Cells exhibit flat discharge curves at low drains. The energy density of the cells is 730 W h/kg or 900 W h/l at room temperature and 950 W h/kg or 1200 W h/l at 60°C (calculated on the basis of all cell components, excluding the case). Storage and discharge tests at 60°C show a capacity loss of 2-5% per month depending on solution composition. This indicates a shelf life of at least 10 years at room temperature. (9 refs.)

77970 Polarization of the lithium electrode in sulfolyl chloride solutions. F.Alessandrini, B.Scrosati (Istituto di Chimica Fisica, Univ. of Rome, Rome, Italy), F.Croce, M.Lazzari, F.Bonino.

J. Power Sources (Switzerland), vol.9, no.3-4, p.289-94 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982).

The growth of the passivating film on a lithium electrode in contact with sulfolyl chloride solutions has been examined by micropolarization and complex impedance measurements. The results tend to confirm the hypothesis of a two-layer film, where probably the first layer is thin and compact and the second layer is porous and defective. (7 refs.)

77971 Li/SOCl₂ cells for high temperature applications. M.Babai, J.Binech (Lithium Battery Plant, Tadiran, Israel).

J. Power Sources (Switzerland), vol.9, no.3-4, p.295-305 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982).

The capacity of Li/SOCl₂ cells operating at temperatures as high as 150°C has been measured at discharge rates up to 5 mA/cm². The results indicate the unique chemical and electrochemical stability of the system, manifested by its ability to be discharged continuously at 150°C for more than 2 months while obtaining 70% of the cell nominal capacity. The capacity-temperature plot shows a maximum at 50°C. Above 50°C the capacity decreases as a result of the increase in the self-discharge current at higher temperature. An anomalous capacity increase is found at temperatures above 100°C. Above this temperature it has been shown that thermal decomposition products may increase the cathodic reaction rate and modify the structure of the passivation layer on the anode surface. Over the 100-150°C temperature range the lithium chloride film morphology, as analysed by SEM, tends to be of a smaller crystal size the higher the temperature. This trend is in opposition to that found at the lower temperature range, e.g. -40 to 70°C. In addition,

the decomposition product, e.g. SO_2 , improves the transport properties of the electrolyte and thus increases the carbon cathode efficiency. (12 refs.)

77972 Li-AgBi(CrO₄)₂ a new highly reliable lithium battery for long service life applications. M.Broussely, J.P.Rivault, J.P.Gabano (Saft-Gipelec, Poitiers, France).

J. Power Sources (Switzerland), vol.9, no.3-4, p.339-44 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). The Li/AgBi(CrO₄)₂ battery system was patented in 1977. It has been studied for several years to obtain a better knowledge of the electrochemical reactions as well as of the discharge characteristics of a prototype cell. An exceptionally low level of self discharge and the use of a very well-known stable electrolyte such as propylene carbonate 1M Li/ClO₄ satisfy the necessary requirements for long service life application: high efficiency was obtained on long time discharges even at high temperature, e.g. 70°C at the two years rate. Performances over a wide range of current drains and temperatures are presented as well as projected results at a very low drain. (5 refs.)

77973 A pre-testable low temperature lithium thermal battery. Hai-De Song, Wen-Rong Lu (Tianjin Inst. of Power Sources, Tianjin, China). *J. Power Sources (Switzerland)*, vol.9, no.3-4, p.417-25 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). The operating temperature of the LiAl/NaAlCl₄/CuCl₂ thermal battery is about 200°C, and it can work in an ambient temperature range of -40 to +50°C. When discharged through a constant resistance of 700 Ω at room temperature, it can operate effectively for 10 min. Prior to use, the battery can be pretested to see whether it is properly assembled and to ensure its performance and reliability. Batteries after pretesting can still be activated without substantially reduced performance. (7 refs.)

77974 A characteristic of separators used in the primary and secondary cells with alkaline electrolyte. J.Dobryszky (Centralnym Lab. Akumulatorow i Ogniwi, Poznan, Poland). *Wiad. Elektrotech. (Poland)*, vol.50, no.13-14, p.408-10 (Nov.-Dec. 1982). In Polish. [received: April 1983]

The role of the separator in primary and secondary cells with alkaline electrolyte, range of separation materials used in alkaline systems, and their characteristic properties are all examined. (5 refs.)

Film forming reaction at the lithium/electrolyte interface See Entry 77977
Raman spectroscopic studies of the structure of electrolytes used in the Li/SOCl₂ battery See Entry 77978

86.30F Secondary cells

77975 The use of the reactive ether, tetrahydrofuran (THF), in rechargeable lithium cells. K.M.Abraham, J.L.Goldman (EIC Labs. Inc., Newton, MA, USA).

J. Power Sources (Switzerland), vol.9, no.3-4, p.239-45 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). The usefulness of tetrahydrofuran (THF) as a cosolvent with 2-methyl-tetrahydrofuran (2-Me-THF)/LiAsF₆ for improving the low temperature rate capability of rechargeable Li cells has been explored. Lithium-titanium disulphide cells utilizing 2-Me-THF/LiAsF₆ blended with 15-50 vol.% THF have shown substantially improved rate characteristics at 0 and -10°C. In addition, the Li electrode in such cells has exhibited practically useful cycling efficiencies. (12 refs.)

77976 The reactivity of organic electrolytes with lithium: mechanistic aspects. V.R.Koch (Covalent Associates Inc., Framingham, MA, USA).

J. Power Sources (Switzerland), vol.9, no.3-4, p.247-51 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). The overall rate of Li-organic electrolyte reactivity is governed by heterogeneous redox chemistry at the Li electrode surface and by homogeneous acid-base chemistry in the bulk. While the former mode of reactivity may lead to protective films, the latter mode invariably results in rapid electrolyte degradation with time and must be considered the most serious source of poor cycling life in rechargeable cells. (18 refs.)

77977 Film forming reaction at the lithium/electrolyte interface. E.Peled (Dept. of Chem., Tel-Aviv Univ., Tel Aviv, Israel).

J. Power Sources (Switzerland), vol.9, no.3-4, p.253-66 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). Active metal nonaqueous systems can be divided into three groups: (a) solid electrolyte interphase (SEI)-free, aqueous-like, active-metal nonaqueous systems, such as aluminium plating baths; (b) metal solvent blue solutions, or solvated electron systems; (c) SEI battery systems. It is concluded that the only type of system that can be applied in primary and secondary lithium batteries is the SEI electrolyte system. The following are presented and discussed: The deposition-dissolution mechanism and the kinetics of SEI electrodes, the effect of several parameters on the resistivity of the SEI, the growth rate of the SEI, the morphology of the overall passivating layer and the voltage delay problem. (33 refs.)

77978 Raman spectroscopic studies of the structure of electrolytes used in the Li/SOCl₂ battery. Y.Bedier, J.Corset (Lab. de Spectrochimie Infrarouge et Raman, CNRS Section de Thiais, Thiais, France), M.C.Dhamelincourt, F.Wallart, P.Barbier.

J. Power Sources (Switzerland), vol.9, no.3-4, p.267-72 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). The importance of the Li/SOCl₂ cell using thionyl chloride as a liquid cathode has given rise to studies of the structure of the electrolytes used in this lithium cell. The electrolytes are made from LiAlCl₄ dissolved in SOCl₂ in which SO₂ is formed during the discharge process. The paper deals with a structural study, using Raman spectroscopy, of solutions of LiAlCl₄ in pure SOCl₂ and SO₂, and in mixtures of both solvents. The complexes [Li(SOCl₂)₂]⁺[AlCl₄]⁻ and [Li(SO₂)₃]⁺[AlCl₄]⁻ were characterized at room temperature in the pure solvents SOCl₂ and SO₂, respectively. In the ternary system LiAlCl₄-SOCl₂-SO₂ the existence of [Li(SO₂, SOCl₂)₂]⁺[AlCl₄]⁻ was established. (4 refs.)

77979 Surface films on lithium in acetonitrile-sulphur dioxide solutions. Y.Geronov, B.Puresheva, R.V.Mosheev (Central Lab. of Electrochem. Power Sources, Acad. of Sci., Sofia, Bulgaria).

J. Power Sources (Switzerland), vol.9, no.3-4, p.273-9 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). The growth of the passive film on Li in acetonitrile-sulphur dioxide solutions of LiBr, LiAsF₆, LiAlCl₄ and LiClO₄ with time has been followed by galvanostatic pulse measurements and SEM observations. It was found that the specific conductivity of the primary film on Li in AN-SO₂-LiBr solutions ($k=4 \times 10^{-9} \text{ ohm}^{-1} \text{ cm}^{-1}$) is practically insensitive to changes in concentration of SO₂ and LiBr. The substitution of Br⁻ by AsF₆⁻ anions in AN-SO₂

electrolytes significantly changes the properties of the film; the rate of growth and the 'steady state' value of the polarization resistance are much higher as compared with those of films obtained on Li in Br⁻-containing electrolytes. Water contamination above 1000 ppm enhances the growth of the passive film as compared with that in 'dry' electrolytes. (6 refs.)

77980 Electrochemical method for studying the reversibility of the lithium intercalation in secondary batteries. F.Dalard, D.Deroo (Lab. d'Energetique Electrochimique, Domaine Univ., Saint Martin d'Heres, France), R.Mauger. *J. Power Sources (Switzerland)*, vol.9, no.3-4, p.321-4 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). In studies of the rechargeability of intercalation material there is no clear demonstration of performance, mainly because experimental data conditions differ between authors. These data depend on material structure, grain size, preparation mode and also cycling procedure. In this article, we present a theoretical study of intercalation during galvanostatic cycling. Experimental results on the intercalation of lithium in MoO₃ are in good agreement with theory. The chemical diffusion coefficient of Li in MoO₃ has been calculated: $D=4 \times 10^{-11} \text{ cm}^2 \text{ s}^{-1}$ at 25°C. (5 refs.)

77981 Chromium oxides as cathodes for lithium cells. Y.Takeda, R.Kanno, Y.Tsuiji, O.Yamamoto (Dept. of Chem., Mie Univ., Tsu, Japan), H.Taguchi.

J. Power Sources (Switzerland), vol.9, no.3-4, p.325-8 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). The performances of organic electrolyte lithium cells with the chromium oxides, Cr₂O₃, CrO₃, Cr₂O₁₂, Cr₂O₅, Cr₆O₁₅, and Cr₃O₈, as cathodes, have been examined. The discharge behaviors of the couples Li/Cr₂O₃, Li/Cr₆O₁₅, and Li/Cr₃O₈ gave satisfactory results, especially in terms of energy density. The highest calculated energy density, based on the weights of the chromium oxides and to a 2.0 V cutoff at 0.5 mA/cm², was 1210 W h/kg for the Li/Cr₃O₈ couple. Further, the performance of a coin-type cell with a Cr₃O₈ cathode was demonstrated, and it was found that the cell exhibited good rechargeability. (5 refs.)

77982 Behaviour of various cathode materials for non-aqueous lithium cells. H.Ikeda, S.Narukawa (Sanyo Electric Co. Ltd., Kobe-shi, Japan).

J. Power Sources (Switzerland), vol.9, no.3-4, p.329-34 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). The reaction mechanisms with Li of various metal oxides, sulfides and a selenide in nonaqueous electrolyte have been studied by the galvanostatic method, X-ray diffraction analysis, and ion-microanalysis. As a result, cell reactions were classified into 3 types. (1) The directly reduced type: cathode materials are reduced directly to metal; CuO, etc. (2) The 2 step reaction type: reaction proceeds through intermediate products: FeS₂. (3) The solid diffusion type, based on the so-called intercalation reaction; MnO₂, LiS₂. These reaction mechanisms are discussed. (9 refs.)

77983 Some critical considerations in the design of multicell lithium-manganese dioxide batteries. K.L.Hampartumian, A.Momchilov, N.Ichev, V.Maney (Central Lab. of Electrochem. Power Sources, Acad. of Sci., Sofia, Bulgaria).

J. Power Sources (Switzerland), vol.9, no.3-4, p.335-8 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). A Li-MnO₂ counterpart of the standard 6F22 Leclanche battery was designed in 3 different versions—paper lined, spiral wound, and layer stacked. The performance of all 3 types was tested according to the IEC discharge conditions, and the results were juxtaposed with Leclanche and zinc-air batteries of identical size and voltage. The merits and shortcomings in terms of capacity, polarization, ability to withstand continuous discharge, and technological back up are discussed. Although all 3 designs displayed superior characteristics as compared with the Leclanche batteries, optimum performance can be achieved by observing several critical requirements concerning the design, materials, and technology. (5 refs.)

77984 Mechanistic studies of reversible layer-type electrodes. J.Rouxel, P.Molinie, L.H.Top (Lab. de Chimie des Solides, Nantes, France).

J. Power Sources (Switzerland), vol.9, no.3-4, p.345-57 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). In layered type intercalation electrodes ions are stored reversibly during the functioning of secondary batteries. The behaviour of the system depends on geometrical and electronic factors. The geometrical factors are concerned with the localization of the ions in the host structure; they deal with average structure determinations and local ordering problems. The diffusion properties of the intercalated ions depend on the site geometry, the population of the Van Der Waals gap, the ionicity of the bonds in the host, the stoichiometry of the host, and the mechanical properties of its slabs. Electrons have to be accommodated by the host. The band structure of the host plays an important role in respect of the ability to intercalate, the phase limit, and the stability of the products. Metal-insulator transition may be induced. Other possible factors such as Jahn-Teller effects have also to be considered. (23 refs.)

77985 Characterization of the chemistry at the anode and cathode in the Li/SO₂ battery system. W.P.Kilroy, C.R.Anderson (Naval Surface Weapons Center, Silver Springs, MD, USA).

J. Power Sources (Switzerland), vol.9, no.3-4, p.397-407 (April-May 1983). (International Meeting on Lithium Batteries, Rome, Italy, 27-29 April 1982). The discharge product of Li/SO₂ cells discharged at 25°C at 1-2 mA/cm² was quantitatively analyzed for sulfite, thiosulfate, and dithionite. Analysis of the lithium anodes of commercial Li/SO₂ batteries by XPS, SAM, SEM, and mass spectroscopy techniques determined the passive film chemistry to be complex, but generally dominated by lithium sulfite and sulfate formation. The anode microstructure and chemistry is inhomogeneous and sensitively dependent upon the state of discharge and the discharge temperature. (8 refs.)

77986 Morphology of the positive active power of the lead-acid accumulator. J.D.Milewski.

Wiad. Elektrotech. (Poland), vol.50, no.13-14, p.406-8 (Nov.-Dec. 1982). In Polish. [received: April 1983]
The morphology of the positive active power of the lead-acid accumulator is discussed. Possibilities of improving the attachment to the cathode in 'calcium' accumulators are also considered. (12 refs.)

77987 Optically enhanced amorphous silicon solar cells. H.W.Deckman, C.R.Wronski, H.Witzke, E.Yablonovitch (Exxon Res. & Engng. Co., Linden, NJ, USA).

Appl. Phys. Lett. (USA), vol.42, no.11, p.968-70 (1 June 1983). The authors describe the first application of optical enhancement to thin-film (~0.75 μ m thick) amorphous silicon solar cells and define cell geometries which maximize enhancement effects. They observed that due to the improved infrared absorption the external AM1 short circuit current increases by 3.0 mA/cm² in cells constructed in accordance with the principles of optical enhancement. (7 refs.)

77988 Polycrystalline X-ray topography (PXT) of a cast silicon photovoltaic cell. R.G.Rosemeier, K.C.Yoo (Univ. of Maryland, College Park, MD, USA), S.M.Johnson.

Mater. Lett. (Netherlands), vol.1, no.5-6, p.194-6 (April 1983). Contiguous (404), and (440)₂ polycrystalline X-ray topographs (PXT) have been obtained simultaneously within a single image for two grains of a cast polycrystalline silicon solar cell. A special two-step twinning orientation relationship between the adjacent grains gives a condition of only faint diffraction contrast being observed at the boundary interface. Stereographic projection analysis was employed to identify simultaneous reflection conditions, and a portable image X-ray intensifier was routinely used to align X-ray images in real time. (7 refs.)

77989 Sunshine Project Solar Photovoltaic Programme and recent activities in Japan. M.Kamimoto, H.Hayashi (Agency of Industrial Sci. & Technol., Ministry of Internat. Trade & Industry, Tokyo, Japan).

Int. J. Sol. Energy (Switzerland), vol.1, no.3, p.185-95 (1982). The Japanese solar photovoltaic program milestone, technological development plans, and their structures in the 'sunshine project' are introduced. Also described is the present status of the solar photovoltaic research and development projects. (no refs.)

77990 Determination of minority carrier lifetime and effective back surface recombination velocity in BSF silicon solar cells from transient measurements. S.C.Jain, S.K.Agarwal, U.C.Ray (Solidstate Phys. Lab., Delhi, India).

Electron. Lett. (GB), vol.19, no.10, p.365-7 (12 May 1983). The method of determining the base lifetime τ_B and the effective surface recombination velocity S_{eff} in a BSF solar cell from the transient decay of open-circuit voltage and short-circuit current is extended to include emitter recombinations. If the emitter recombinations in modern Si solar cells are neglected in interpreting the experimental data, the experimental value of S_{eff} is found to be in large error. (11 refs.)

77991 Solar cells. Present state and development. D.Teodorescu.

Elektr. Masch. (Germany), vol.62, no.4, p.105-12 (April 1983). In German. The limiting factor in solar installations is still the very high cost of solar cells. However, this is anticipated to come down significantly in the coming years. Present development trends are to put to terrestrial use astronautics experience in the production of solar generators which could make a greater contribution to the energy balance. But this entails cost reductions in the production of solar cells, improving their efficiency and life span. This also raises problems of energy storage, of improving technological processes for the production of active materials for solar cells, and of integrating such technologies into conventional ones to bring down production costs, giving great scope for CdS and similar low cost solar cells. Solar and thermo-electric solar installations are described and diagrammatically illustrated. (21 refs.) P.F.K.

77992 A new type of monolithic double junction solar cell. C.Flores.

Electron. Oggi (Italy), no.3, p.227-32 (March 1983). In Italian. A new type of monolithic solar cell (TTC2) is described highlighting technology and performance. The new cell consists of one p-n GaAs junction (1.4 eV) coupled to a second n-p junction of GaAlAs (1.7 eV). The zones are interconnected through a n-layer but are electrically independent forming a 3-terminal device similar to a p-n-p transistor. Resultant efficiency is 20.5% at a solar concentration of 80 decreasing to 16.2% at 500 concentration. Technology performance and application details are included. (8 refs.) T.H.

77993 The influence of hydrogen ion bombardment on the photovoltaic properties of Cu/Cu₂O Schottky barrier solar cells. R.J.Iwanowski, D.Trivich (Dept. of Chem., Wayne State Univ., Detroit, MI, USA).

Radiat. Eff. Lett. Sect. (GB), vol.76, no.3, p.87-92 (1983). The influence of hydrogen ion bombardment on the photovoltaic properties of Cu/Cu₂O Schottky barrier solar cells was investigated. Two main cases of junction formation process were considered depending on the sequence of applied procedures: thermal evaporation of thin Cu layer and irradiation of the substrate by H⁺ ion beam. (5 refs.)

77994 A three-dimensional double junction GaAs/GaAlAs cascade solar cell. C.Flores (CISE SpA, Milano, Italy).

IEEE Electron Device Lett. (USA), vol.EDL-4, no.4, p.96-9 (April 1983). Describes the fabrication process and performances of a new type of monolithic solar cell with two junctions and bandgaps of 1.4 eV (GaAs) and 1.69 eV (GaAlAs) respectively, with the novel feature of only four epitaxial layers. The structure is a three-terminal device similar to a p-n-p transistor with a thick base. For the first prototypes, an overall conversion efficiency of 20.5 percent has been measured at 80 suns. It is expected that further optimization steps can lead to a conversion efficiency of 25 percent AM 1.5 for this structure. (8 refs.)

77995 Physics of BSF solar cells at high levels of illumination. S.R.Dhariwal, R.Gadre, R.K.Mathur (Dept. of Phys., Government Coll., Ajmer, India).

IEEE Electron Device Lett. (USA), vol.EDL-4, no.4, p.105-7 (April 1983). The theory of BSF solar cells by Fossum et al. (see IEEE Trans. Electron Devices, vol.ED-27, no.4, p.785-91, 1980) is extended to high levels of injection. For such intensities, more general J_{sc} - V_{oc} relationships are derived which show deviation from the ideal exp (qV/kT) relationship. (5 refs.)

77996 Use of tin oxide as an inexpensive antireflection coating for p on n polycrystalline silicon solar cells. B.C.Chakravarty, S.N.Singh, B.K.Das (Div. of Materials, Nat. Phys. Lab., New Delhi, India).

IEEE Electron Device Lett. (USA), vol.EDL-4, no.5, p.138-9 (May 1983). The potential of tin oxide as an inexpensive antireflection (AR) coating for polycrystalline silicon solar cells has been investigated. Undoped tin oxide films of a desired thickness were deposited over p-n polycrystalline silicon solar cells by spray pyrolysis of an alcoholic solution of hydrated stannic chloride at 500°C. Evaluation of cell performance before and after this AR

coating showed that the AR coating is highly compatible with the polycrystalline silicon solar cells. About 40-50 percent improvement in the short-circuit current of p-n polycrystalline cells has been measured. The coating may be highly suited to large-scale production of low-cost polycrystalline silicon solar cells for terrestrial application. (7 refs.)

77997 Computer simulation of amorphous silicon based alloy p-i-n solar cells. M.Hack (Energy Conservation Devices Inc., Troy, MI, USA), M.Shur.

IEEE Electron Device Lett. (USA), vol.EDL-4, no.5, p.140-3 (May 1983). The authors report on the results of a computer simulation of amorphous silicon-based alloy p-i-n solar cells based on the complete set of transport equations. The model takes into account the spatial and energy variations of the localized state spectrum, nonuniform doping profiles, and nonuniform optical excitation. The computed dark and light current-voltage characteristics are in good agreement with experimental data. The results suggest that carrier back diffusion is not a significant effect in optimized p-i-n devices and that the open circuit voltage is determined by the recombination current. Also shown is the importance of residual boron doping in the intrinsic layer for cells illuminated through the n⁺-layer, and that hole transport limits device performance. (18 refs.)

77998 Efficiency of the a-Si:H solar cell and grain size of SnO₂ transparent conductive film. H.Ida, N.Shiba, T.Mishuku, H.Karasawa, A.Ito (Tech. Lab., Taiyo Yuden Co. Ltd., Gumma, Japan), M.Yamanaka, Y.Hayashi.

IEEE Electron Device Lett. (USA), vol.EDL-4, no.5, p.157-9 (May 1983). The relationship between average grain size on the surface of SnO₂ transparent conductive film and conversion efficiency of the a-Si:H solar cell was investigated. a-Si:H solar cells were fabricated on SnO₂/glass substrates with various grain sizes. The cell structure was glass/p(SiC)-i-n/Al and the effective cell area was 4x10⁻² cm². The reflectivity from the glass substrate was reduced to about 7 percent with increasing the grain size from 0.1 to 0.8 μ m, and the short-circuit current was increased from 12 to 14 mA/cm². A 7.9 percent of conversion efficiency was achieved using milky SnO₂ film of 0.4- μ m average grain size at AM-100 mW/cm². (2 refs.)

77999 The spectral response of BSF silicon solar cells fabricated through masked ion implantation. A.Silard (Dept. of Electronics, Polytech. Inst., Bucharest, Romania), R.Marinescu, M.Tazlauanu.

IEEE Electron Device Lett. (USA), vol.EDL-4, no.6, p.164-6 (June 1983). Presents the main peculiarities of the spectral response of back-surface-field (BSF) silicon solar cells fabricated through masked ion implantation of the n⁺-p junction. The emphasis is on the shift of maximum responsivity toward the visible spectrum and on the large bandwidth of these n⁺-p-p⁺ optical sensors. The dependence of these parameters on technological parameters are outlined in the communication. (4 refs.)

78000 Flash-lamp annealing of ion-implanted silicon and its application to solar cells. A.Usami, N.Yoshida, Y.Inoue (Dept. of Electronics, Nagoya Inst. of Technol., Nagoya, Japan).

IEEE Electron Device Lett. (USA), vol.EDL-4, no.6, p.166-8 (June 1983). Xe-lamps were used to anneal p⁺-implanted silicon. The redistribution of implanted dopants does not occur by flash annealing. The substrate-orientation dependence of electrical activity of implanted dopants between (100) and (111) silicon is found. Solar cells fabricated by p⁺-implantation at 25 keV and annealing by the lamp energy density of 28 J/cm² show an efficiency of about 10.4 percent (AM 2) without AR coating and BSF structures. (5 refs.)

78001 Interfacial stability of SnO₂/n-Si and In₂O₃/Sn/n-Si heterojunction solar cells. H.P.Maruska, A.K.Ghosh, D.J.Eustace, T.Feng (Corporate Res. Lab., Exxon Res. & Engng. Co., Linden, NJ, USA).

J. Appl. Phys. (USA), vol.54, no.5, p.2489-94 (May 1983). High efficiency SnO₂/n-Si and In₂O₃/Sn/n-Si solar cells have been fabricated which when encapsulated in EVA (ethylene vinyl acetate copolymers) and kept at temperatures below 200°C exhibit long-term stability. However, in the absence of proper encapsulation or at high temperatures, it is possible for the properties of heterojunction SnO₂/n-Si and In₂O₃/Sn/n-Si solar cells to suffer degradation through two distinct mechanisms, one optical and the other thermal in nature. In either case, losses in V_{oc} can be correlated with changes in the dark current-voltage characteristics: light stress increases the dark saturation current J_0 , while heat stress decreases the diode quality factor n . Both degradation mechanisms are related to changes in the stored charges in the SiO_x interphase region between the conducting oxide and the silicon. The thermal process is only relevant for temperatures above 300°C, while the optical process is only evidenced if ultraviolet light is incident on the cell. Thus, cells kept at $T < 200^\circ\text{C}$ behind a suitable UV-absorbing filter remain stable indefinitely. (17 refs.)

78002 High efficiency in 'semithermal' solar energy converters. R.T.Ross (Dept. of Biochem., Ohio State Univ., Columbus, OH, USA).

J. Appl. Phys. (USA), vol.54, no.5, p.2883-4 (May 1983). A photonic device in which the excited carriers thermally equilibrate both among themselves and with the lattice, but maintain distinct chemical potentials in the ground and excited bands, has the same high ideal efficiency as a converter in which only the carriers are hot. Because the hot carriers need only be removed from the absorber faster than band-to-band transitions, such a 'semithermal' device should be more practical than devices in which carriers may not equilibrate with the lattice. (6 refs.)

78003 Photovoltaic and electrical properties of n-CdS/p-Si heterojunction solar cells. T.Suda, A.Kuroyanagi (Dept. of Electronics, Inst. of Vocational Training, Kanagawa, Japan), S.Kurita.

J. Cryst. Growth (Netherlands), vol.61, no.3, p.494-8 (April-May 1983). Heterojunction solar cells of CdS/In/Si have been fabricated by electron-beam evaporation of CdS, and their electrical and photovoltaic properties are studied. The forward I-V characteristics of these cells are in good agreement with the tunneling model. To obtain an optimum condition for cell fabrication several parameters have been varied; such as substrate temperature, amount of In doping in CdS, and annealing temperature in various ambients (H₂, N₂ and S vapor). The CdS/In/p⁺-Si cell shows no degradation at room temperature in air over 30 months, whereas the CdS/In,Ag/p⁺-Si cell shows rapid degradation after 3 months. From the DLTS measurements using a computer controlled digital system five electron traps have been measured in an evaporated CdS/In/p⁺-Si cell. (18 refs.)

78004 Research on polycrystalline thin-film photovoltaic devices. A.M.Hermann, L.Fabick (Solar Energy Res. Inst., Golden, CO, USA).

J. Cryst. Growth (Netherlands), vol.61, no.3, p.658-64 (April-May 1983). The United States Department of Energy Polycrystalline Thin-Film Photovoltaic Device Program encompasses materials and device research on a variety of compound semiconductors with emphasis on II-VI compounds and II-VI ternary analogs. The preparation (emphasizing thin-film deposition) and characterization of semiconducting materials such as Cu₂-S, Cu₂-Se, CdTe and CuInSe₂ are covered. Photovoltaic device characteristics of these absorbers with heterojunction partners such as CdS are discussed. Excitement in the

program has been generated by recent progress in the (Cd,Zn/S)/CuInSe₂ device area. Unencapsulated (Cd,Zn)/S/CuInSe₂ cells have been subjected to more than 6000 h of accelerated stability testing with no measurable degradation in photovoltaic performance. Other program highlights include fabrication of a hybrid CdS/Cu₂S device (evaporated CdS, sputtered Cu₂S) all-sputtered CdS/Cu₂S cell. Preliminary data are presented on the achievement of intrinsically stable high-efficiency (>9%) wet-processed CdS/Cu₂S cells. A 5.3% (AM1) CVD Au/n-CdTe Schottky barrier cell is described. (41 refs.)

78005 Efficient pAl_{0.5}Ga_{1.5}As-pGaAs:Si-nGaAs photocells for use in intense sunlight. A.M.Allakhverdiev, B.V.Egorov, V.M.Lantratov, S.I.Troshkov (A.F. Ioffe Physicotech. Inst., Acad. of Sci., Leningrad, USSR). *Sov. Phys.-Tech. Phys. (USA)*, vol.27, no.11, p.1425-6 (Nov. 1982). Translation of: *Zh. Tekh. Fiz. (USSR)*, vol.52, no.11, p.2312-14 (Nov. 1982). [received: May 1983]

The authors report findings from a study of highly efficient solar photocells based on nGaAs-pGaAs-pAl_{0.5}Ga_{1.5}As heterostructures. The authors were able to increase the thickness of the p-type GaAs layer without increasing the recombination losses by preparing the layer from a silicon-doped melt (solution). (6 refs.)

78006 Variable minority carrier transport model for amorphous silicon solar cells. H.Okamoto, H.Kida, S.Nonomura, Y.Hamakawa (Faculty of Engng. Sci., Osaka Univ., Osaka, Japan). *Sol. Cells (Switzerland)*, vol.8, no.4, p.317-36 (May 1983).

A new carrier transport model describing the photovoltaic characteristics of amorphous silicon (a-Si) p-i-n junction (where i denotes intrinsic material) solar cells is proposed. In the model, the operative i layer is divided into two regions at a variable boundary; in each region, either electrons or holes are assumed to act just like the minority carriers dominating the carrier recombination rate. Based on this variable minority carrier transport model, comprehensive interpretations of the carrier collection efficiency spectra and dark and illuminated current density-voltage characteristics are given in terms of several basic parameters responsible for them, i.e. mobility-lifetime products, effective surface recombination velocities and conductivities at the p-i and i-n interfaces. The model presented can be used not only for explaining and predicting the photovoltaic properties but also for evaluating these parameters in actual a-Si solar cells. Furthermore, an identification of the relevant properties in various types of a-Si solar cell enables us to make clear how to design and fabricate the cells in order to attain higher photovoltaic performances. (25 refs.)

78007 Importance of the emitter in thin back-surface field solar cells. S.K.Mehta, S.C.Jain (Solid State Phys. Lab., Delhi, India). *Sol. Cells (Switzerland)*, vol.8, no.4, p.337-53 (May 1983).

The variation in the short-circuit current density J_{sc} , the open-circuit voltage V_{oc} and the efficiency η with the base thickness of an n⁺-p-p⁺ back-surface field (BSF) solar cell with a resistivity of 10 Ω cm is reported for 1 sun air mass 0 illumination. The effects of different emitter dark saturation current densities J_{E0} and different base diffusion lengths L_B on the variation in V_{oc} with the change in base thickness were calculated. The effective surface recombination velocity S_{eff} at the edge of the low-high junction is calculated as a function of the thickness w_H of the high region for various values of the recombination velocity S_r at the back contact. The temperature degradation coefficient of V_{oc} for a BSF cell was calculated with the band gap narrowing in both the emitter and the high region taken into account. (32 refs.)

78008 Analysis of the effects of the lateral resistance of the superficial zone on the current voltage characteristics of linear gridded solar cells. D.Lincot, M.Barbe, G.Cohen-Solal, F.Bailly (Lab. de Phys. des Solides, Meudon Bellevue, France). *Sol. Cells (Switzerland)*, vol.8, no.4, p.361-9 (May 1983). In French.

The paper analyses the influence of sheet series resistances on the terminal current-voltage characteristics of linear gridded solar cells. Analytical relations are established, in particular for the case of significant losses due to sheet resistances under illumination. These relations permit solar cell behaviour to be described quantitatively and allow their characteristics to be optimized. (10 refs.)

78009 Model calculations for silicon inversion layer solar cells. M.A.Miller, L.C.Olsen (Joint Center for Graduate Study, Richland, WA, USA). *Sol. Cells (Switzerland)*, vol.8, no.4, p.371-95 (May 1983).

Theoretical models for the current versus voltage characteristics of inversion layer (IL) solar cells are developed and used in modelling calculations. Two-dimensional carrier transport from the base region to the inversion layer and collector grid is taken into account by modelling the cell as a series of infinitesimally thin slices which supply current to the inversion layer and by solution of the two-dimensional diffusion equation for minority carriers. Significant device parameters are identified and model calculations are carried out over a range covering most physically realizable values for these parameters for p-type silicon-based devices. Conditions necessary for good device performance are identified and the results of poor device parameters discussed. Finally, modelling calculations of IL solar cells carried out by others are discussed and compared with those presented here. (39 refs.)

78010 Barrier height enhancement in semiconductor-insulator-semiconductor solar cells due to surface states and insulator charges. N.R.Saha, D.Roychoudhuri, P.K.Basu (Inst. of Radio Phys. & Electronics, Calcutta, India). *Sol. Cells (Switzerland)*, vol.8, no.4, p.397-401 (May 1983).

Studies of the changes in the barrier heights in both sputtered and sprayed n-ITO-SiO₂-pSi cells with changes in the positive fixed charges Q_{fix}^+ , in the substrate doping level N_A and in the thickness δ of the interfacial layer, and identifies values of these parameters which will increase the barrier height. In addition, the voltage drop across the insulator is studied with various control parameters. (9 refs.)

78011 Evaporation of CuCl and CuCl₂ for the fabrication of Cu₂S/CdS thin film solar cells. M.Burgelman, A.De Vos (Lab. voor Elektronika en Meettech., Rijksunivers. te Gent, Ghent, Belgium). *Thin Solid Films (Switzerland)*, vol.102, no.4, p.367-74 (29 April 1983).

The so-called dry method for the fabrication of Cu₂S/CdS thin film solar cells uses a thin CuCl film, in order to convert the surface layer of the CdS film into Cu₂S. Usually, the CuCl film is deposited by evaporation of freshly prepared CuCl powder. The authors investigate the influence of contamination of this evaporation material by CuCl₂ and by CuCl₂·2H₂O. The experiments show that about 99% of these contaminants decompose into CuCl during the evaporation process. (20 refs.)

78012 Amelioration des performances de la pile solaire au silicium de grand diametre (Amelioration of the performance of a large diameter silicon solar pile). D.Diguet.

Report EUR 8145 FR, Comm. European Communities, Luxembourg (1982), 48 pp. In French. Contract 426-78-3 ESF.

Presents an interim report on a long term project, expected to last until 1990. The introduction describes the various phases which are planned followed by a description of the actual way in which various parts of the work will actually be carried out. The results obtained to date are reported including analysis methods, comparative analysis, and a simplified method of preparing substrates. Serialised contacts are studied as is the subject of connection welding. Some analyses of results are given, together with thoughts on the production of the electrical equipment. The final section is on cell interconnections.

78013 Realisation et caracterisation de cellules solaires Cu₂S-CdZnS (Realisation and characterisation of Cu₂S-CdZnS solar cells). M.Cadene.

Report EUR 8153 FR, Comm. European Communities, Luxembourg (1982), 46 pp. In French. Contract 431-78 ESF.

The preparation, by different evaporative methods, of Cd_{1-x}Zn_xS films with values of x between 0.04 and 0.2 is described. Their intrinsic and extrinsic properties (crystallisation, carrier density, mobility, trap levels etc.) as a function of Zn content are studied by independent optical, electrical and optoelectronic methods. The process of topotaxial growth of Cu₂S film is studied and the photocurrents and photovoltages of backwall CdZnS-Cu₂S cells made from these films are measured. The spectral responses of pure CdS, Cd_{0.98}Zn_{0.02}S and Cd_{0.95}Zn_{0.05}S cells formed by double-crucible evaporation, and of a Cd_{0.92}Zn_{0.08}S cell evaporated from the solid solution, are plotted and discussed. (15 refs.)

78014 New directions in solar array development. J.Scott-Monck (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.7-12

This paper presents a broad overview of current and near term solar array technology that would be suitable for space use in the event that NASA, commercial and US defense planners decide to aggressively pursue and exploit the advantages of space photovoltaics. (16 refs.)

78015 Technology components of solar arrays for space platforms. K.Bogus (European Space Res. & Technol. Centre, ESA, Noordwijk, Netherlands).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.13-20

Space platform concepts are categorised in the frame of the European space programme into four classes containing near-term missions and follow-up generations. Common and distinguishing requirements on the solar array subsystem in each of the four classes are identified leading to a definition of photovoltaic technology development requirements. Current space photovoltaic technology activities in Europe which respond to these requirements are described and activities for future space platform applications are assessed. (19 refs.)

78016 Status of AlGaAs/GaAs heteroface solar cell technology. W.P.Rahilly (Air Force Wright Aeronautical Labs., Wright-Patterson Air Force Base, OH, USA), B.Ansbaugh.

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.21-4

The paper reviews the various GaAs solar cell programs that have been and are now ongoing which are directed at bringing this particular technology to fruition. The discussion emphasizes space application—both concentrator and flat plate. The rationale for pursuing GaAs cell technology is given along with the different cell types (concentrator, flat plate), approaches to fabricate the devices, the hybrid cells under investigation and approaches to reduce cell mass are summarized. The outlook for the use of GaAs cell technology is given within the context for space application. (10 refs.)

78017 Solar array shuttle flight experiment—hardware development and testing. R.V.Elms (Lockheed Missiles & Space Co. Inc., Palo Alto, CA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.25-30

The paper reports on the fabrication and ground testing of (a) a large area, light-weight, flexible substrate developmental solar array wing that has been built for NASA-MSFC (Contract NAS8-31352) and of (b) the supporting structure and data acquisition system (DAS) which, with the wing will be flown in the shuttle as an experiment in 1984. The experiment will verify the dynamics, thermodynamic, and electrical performance predictions of the array wing and will demonstrate the structural capability of the array wing for Orbiter launch and re-entry environments. The accommodation of the Shuttle payload requirements has resulted in several array wing and operation modifications since the ground demonstration of the array wing in the technology development program. The experiment hardware verification program was designed to minimize costs and risk of experiment performance degradation while maintaining shuttle and crew safety. (2 refs.)

78018 Technical aspects of the INTELSAT V solar array. H.E.Pollard, W.R.Baron (Ford Aerospace & Communications Corp., Palo Alto, CA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.31-5

The INTELSAT V solar array is the largest rigid solar array used for a commercial communication satellite. The paper describes salient technology applications of the electrical design, development and manufacture of the INTELSAT V solar array. The circuits including cells, interconnects and wiring are being assembled using solderless welding techniques; the first solar array of this size to do so. Special welding process controls are described including monitor of electrical pulse, resistance and head pressure which provide the quality control to assure satisfactory welds. With the extensive use of solderless cells, various techniques were employed to ensure humidity resistance. The use of the Scanning Auger Microprobe as well as X-ray fluorescence for Palladium measurements are summarized. The electrical and environmental test program for the project is reviewed. (3 refs.)

78019 New component development for multi-100 kW low-cost solar array applications. G.J.Pack, J.A.Mann (Lockheed Missiles & Space Co. Inc., Sunnyvale, CA, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.36-8
Studies of the costs and performance of flexible arrays have shown that the most dramatic reductions in the \$/Watt figure of merit are achieved by increasing performance. An examination of those properties that contribute to array performance indicated areas where radical changes in current design practice and philosophy would result in significant cost and performance impacts. To take advantage of the predicted cost reductions, modules were fabricated and tested that had ultra-thin superstrates as a load carrying member and large area dielectric wraparound (DWA), gridded back surface and copper contacted solar cells. (no refs.)

78020 Design and performance trades for a miniaturized photovoltaic concentrator array. R.E.Patterson, H.S.Rauschenbach, M.D.Cannady (TRW Space & Technol. Group, Redondo Beach, CA, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.39-44
A miniaturized Cassegrainian concentrator module for space applications has been designed, assembled, and tested. Results to date support technical feasibility. Trade studies have shown that the performance of an earlier selected base-line design using silver coated, 0.25 mm electroformed nickel optics with circular elements arranged in a hexagonal close packed configuration can be improved. Specific power values of 27.3 W/kg BOL and 25.0 W/kg after 5 years in LEO have been projected at the 4 kW array level. At the 500 kW level, 20 W/kg BOL had been predicted earlier for the same cell efficiency. (8 refs.)

78021 Advances in solar cell welding technology. L.G.Chidester, D.R.Lott (Lockhead Missiles & Space Co. Inc., Sunnyvale, CA, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.51-6
In addition to developing the rigid substrate welded conventional cell panels for an earlier US flight program, LMSC recently demonstrated a welded lightweight array system using both 2x4 and 5.9x5.9 cm wraparound solar cells. This weld system uses infrared sensing of weld joint temperature at the cell contact metallization interface to precisely control weld energy on each joint. Modules fabricated using this weld control system survived low-earth-orbit simulated 5-year tests (over 30000 cycles) without joint failure. The data from these specifically configured modules, printed circuit substrate with copper interconnect and dielectric wraparound solar cells, can be used as a basis for developing weld schedules for additional cell array panel types. (2 refs.)

78022 Achievement and properties of self-supporting polysilicon solar cells made from RAD ribbons. C.Belouet, C.Hervo, M.Mautref, C.Fages, J.Hervo (Centre de Recherches, Compagnie Generale d'Electricite, Marcoussis, France).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.80-5
The paper reports on the general status of the RAD growth process. The growth achievements and the consequences of the burn-off of the carbon ribbon after growth are briefly discussed. Emphasis is placed on the characteristics of the solar cells made from the self-supported layers obtained from the burn-off step; it is shown that i) these characteristics are impaired mainly by trapping effects and ii) low-temperature annealings at 430°C considerably reduce the activity of traps. It is concluded on the basis of a comprehensive study that AM₁ conversion efficiencies in the 11 to 13% range, should be obtained provided the trapping effect by obviated. (11 refs.)

78023 Solar array system for solar maximum mission. R.A.Meese, L.J.Goldhammer (Hughes Aircraft Co., Space and Communications Group, Los Angeles, CA, USA), D.K.McCarthy.
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.96-101
On 14 February 1980, NASA's Goddard's Solar Maximum Mission (SMM) observatory was launched from the Eastern Test Range, Florida. Approximately 70 minutes after launch, having reached its planned circular orbit of 315 n.m., 28.5° inclination, the Solar Array System (SAS) was successfully deployed. The system, has provided all electrical power required during the observatory's two-year mission which was directed toward scientific exploration of the sun's activity. The SAS is the first solar array to be fully compatible with the power module of NASA's multimission modular spacecraft (MMS) and is the first array to employ solar cells whose covers are bonded by means of FEP Teflon. This paper describes the SAS design, its unique features, and the results of its successful in-orbit operation. (1 ref.)

78024 Research on polycrystalline silicon solar cells: goals and accomplishments. J.B.Milstein, R.W.Hardy, Y.S.Tsuo (Solar Electric Conversion Res. Div., Solar Energy Res. Inst., Golden, CO, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.119-22
Reviews the results obtained in the polycrystalline silicon solar cell task area at the Solar Energy Research Institute (SERI) since the last IEEE Photovoltaic Specialists Conference, and presents a description of the goals which are expected to be achieved in the next year and beyond. Some of the future program elements are presented in general terms, in view of Requests for Proposals that are presently in process. (16 refs.)

78025 Thin film polycrystalline silicon solar cell. A.Z.Lin, Z.Q.Fan, H.Y.Sheng, X.W.Zhao (General Res. Inst. of Non-Ferrous Metals, Beijing, China).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.140-5
Epitaxial solar cells of different types are studied by taking the refined metallurgical grade silicon as original material, including the unidirectionally recrystallized silicon on the graphite substrate and then deposition of a thin silicon film to form the p-n junction. Also included are the horizontally and unidirectionally solidifying polycrystalline ingots in a graphite crucible and Czochralski-grown ingots, which were cut into wafers and then a silicon film deposited to form the p-n junction. Some electrical characteristics of these different types of solar cell are described. The impurity situations of the cells were analyzed, including the measurements of DLTS. (11 refs.)

78026 Large area, low cost space solar cells. J.Kukulka, P.A.Iles (Applied Solar Energy Corp., City of Industry, CA, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.146-9
Describes cost effective production-ready space solar cells which can meet the requirements for use on the space shuttle and other large space missions. Actual yield and performance data for these cells, as well as cost comparisons between these and standard space cells are included. (3 refs.)

78027 Large area space solar cell assemblies. M.J.Nowlan, M.B.Spitzer (Spire Corp., Bedford, MA, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.150-5
Results of the development of a 34.3 cm² space solar cell and integral glass cover are presented. Average AM0 cell efficiency is 14%. The cell design includes a high performance back surface reflector yielding a thermal alpha of approximately 0.66. A novel process is described which integrates cell fabrication and encapsulation thereby achieving a reduction of encapsulation cost. Test results indicate the potential of this new technology. (6 refs.)

78028 Recent advances in thin silicon solar cells. F.Ho, P.A.Iles (Applied Solar Energy Corp., City of Industry, CA, USA), H.Curtis, C.Baraona.
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.156-9
Reviews recent progress in thin (2-4 mils, 50-100 μm) silicon solar cells, in three areas: preparation for production processing, coplanar back contact, and formation of cells with very low solar absorptance (α_s < 0.66). (13 refs.)

78029 Mechanical wraparound contacted cell for low cost space arrays. N.Mardesch, D.Joslin, D.Michaels (Spectrolab, Inc., Sylmar, CA, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.160-3
Presents the advantages, performance, reliability and cost of a mechanical wraparound contact on a large area solar cell. The wraparound contact consists of a silver ribbon laminated to the metallisation of the back of a solar cell with an insulating acrylic-Kapton-acrylic sandwich and wrapped around the edge to the N⁺ metallisation and welded. The wraparound contact can increase the cell cost by approximately 20%, which must be offset by the panel assembly savings. (1 ref.)

78030 Engineering design for a photovoltaic central station power plant using tracking concentrator photovoltaic arrays. E.J.Simburger (Aerospace Corp., El Segundo, CA, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.164-9
A preliminary engineering design has been developed for a photovoltaic central station power plant that utilizes tracking concentrator photovoltaic (PV) arrays. In previous work in this programme power plant design using flat plate photovoltaic technology was developed. The principles developed in the earlier work have now been applied to the design that uses tracking concentrator photovoltaic arrays. The approach taken was to use electric utility design practices wherever possible and to provide sufficient definition of equipment to permit subsequent preparation of engineering cost estimates. (9 refs.)

78031 An advanced photovoltaic system simulator to demonstrate the performance of advanced photovoltaic cells and devices. L.Mrig, R.DeBlasio (Solar Energy Res. Inst., Golden, CO, USA), G.A.O'Sullivan, R.P.Tomko.
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.199-204
Describes a photovoltaic system simulator for characterizing and evaluating the performance of advanced photovoltaic cells, modules, and arrays as well as for simulating the operation of advanced conceptual photovoltaic systems. The system simulator is capable of extrapolating the performance from a single laboratory cell, or of a module to power levels up to 10 kW. The major subsystems comprising the system simulator are (1) Solar Array Simulator, (2) Power Conditioning Unit, (3) Load Controller and Resistive Load Unit, (4) Data Acquisition and Control Unit, and (5) Cell Test Bed. (1 ref.)

78032 Deep level defects and annealing studies in one-MeV electron irradiated (AlGa)As-GaAs solar cells. Sheng S. Li (Univ. of Florida, Gainesville, FL, USA), W.L.Wang, R.Y.Loo, W.P.Rahilly.
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.211-15
Investigates the deep-level defects induced by one-MeV electron irradiation in the (AlGa)As-GaAs solar cells subject to different irradiation and annealing conditions. Both undoped and Sn-doped GaAs cells are fabricated. For Sn-doped GaAs cells, electron irradiation is performed for fluences of 1x10¹⁴, 1x10¹⁵, and 2x10¹⁶ e/cm², and subsequently annealed at 230°C for 10, 20, 30 and 60 minutes. In addition, irradiation is also made on Sn-doped cells with flux rates of 4x10¹⁰ and 2x10¹¹ e/cm²-s and at cell temperatures of 150 and 200°C. For undoped cells, irradiation is made at 200°C for two fluences (1x10¹⁴ and 1x10¹⁵ e/cm²). DLTS and C-V measurements are performed on these cells to determine the defect and recombination parameters. Details of the results are presented. (9 refs.)

78033 Radiation damage in front and back illuminated high resistivity silicon solar cells. I.Weinberg, C.Goradia, C.K.Swartz, H.W.Brandhorst, Jr. (NASA, Lewis Res. Center, Cleveland, OH, USA).
Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.216-21
Radiation induced degradation, in front and back illuminated 84 and 1250 ohm-cm n⁺pp⁺ silicon solar cells, was determined and cell performance interpreted using calculated optically injected charge distributions and cell voltage components. The 84 ohm-cm cell degraded less when illuminated from the front or n⁺ side compared to that when illuminated from the back or p⁺ side. On the other hand, the 1250 ohm-cm cell degraded less when back illuminated. It was concluded that, in addition to the usual mechanisms leading to decreased collection efficiencies, loss of conductivity modulation is a major cause of radiation damage in high resistivity silicon solar cells. These results suggest that radiation damage to high resistivity n⁺pp⁺ cells can be decreased by increasing cell collection efficiency and illuminating the cells from the p⁺ side. (4 refs.)

78034 Comparative values of advanced space solar cells. L.W.Slifer, Jr. (Goddard Space Flight Center, Greenbelt, MD, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.222-7.

This methodology for deriving a first order dollar value estimate for advanced solar cells consists of defining scenarios for solar array production and launch to orbit and the associated costs for typical spacecraft, determining that portion affected by cell design and performance and determining the attributable cost differences. Break-even values are calculated for a variety of cells; confirming that efficiency and related effects of radiation resistance and temperature coefficient are major factors; array tare mass, packaging and packing factor are important; but cell mass is of lesser significance. Associated dollar values provide a means of comparison. (10 refs.)

78035 The metal interconnected cascade solar cell. R.A.LaRue, G.P.Borden, M.J.Ludowise, P.E.Gregory, W.T.Dietze (Varian Associates Inc., Palo Alto, CA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.228-30.

A cascade cell employing a new type of interconnect is described. It uses a groove etch and metallisation process to connect the base of the top cell to the emitter of the bottom cell. The best cell yielded 21.3% efficiency under conditions of AM3, 130 suns, 50°C, with the result not corrected for grid coverage. Other features include a 1.2-micron thick 1.82-Ev AlGaAs top cell with a BSF under the base and an n/p heteroface GaAs bottom cell that is stable during top cell growth. (7 refs.)

78036 Effects of indirect bandgap top cells in a monolithic cascade cell structure. H.B.Curtis, M.P.Godlewski (NASA, Lewis Research Center, Cleveland, OH, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.231-5.

The effect of having a slightly indirect top cell in a three junction cascade monolithic stack is calculated. The minority carrier continuity equations are utilized to calculate individual junction performance. Absorption coefficient curves for general III-V compounds are calculated for a variety of direct and indirect gap materials. The results indicate that for a small excursion into the indirect region, (about 0.1 eV), the loss of efficiency is acceptably small (<2.5 percent) and considerably less than attempting to make the top junction a smaller direct bandgap. (11 refs.)

78037 End-of-life aspects of BSF technology for thin silicon solar cells.

K.-E.Rasch, K.Roy, K.-H.Tentscher (AEG-Telefunken, Heilbronn, Germany).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.236-9.

A matrix of solar cells (100 and 200 microns, 10 ohm-cm crucible grown) was fabricated to identify BSF technology with highest effectiveness under BOL and EOL conditions. The BSF structure was formed by boron diffusion, boron ion implantation, evaporated aluminium alloying and screen printed aluminium firing. The BOL and EOL characteristics after electron irradiation at fluences up to 1×10^{15} e/cm² are presented. (3 refs.)

78038 An alternate approach for low cost space cells. P.M.Stellar, T.F.Miyahira (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.240-5.

Silicon solar cells manufactured for the terrestrial market are examined as a potential low cost option for low earth orbit space flight use. The results of simulated space environmental testing of representative samples are reported and discussed. It is shown that although the terrestrial cells are compatible with most space use requirements significant deficiencies still exist. Cell modifications are discussed which would enhance the space applicability of the various cells examined. In most cases these are expected to be of minimal cost impact. Concern for contact/interconnector designs capable of surviving 30000 thermal cycles (corresponding to five years in LEO) however, needs to be resolved for the large area terrestrial devices. (4 refs.)

78039 Guidelines and methodology for design and analysis of advanced PV technology systems. T.J.Lambarski, C.A.Irby, M.G.Semmens (BDM Corp., Albuquerque, NM, USA), L.Mrig, R.DeBlasio.

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.289-94.

The paper presents the technologies chosen for conceptual design development, the methodology used, results of the system design and analysis, and conclusions and guidelines based on the results. (9 refs.)

78040 The intensity dependence of surface recombination in high concentration solar cells with charge induced passivation. J.L.Gray, R.J.Schwartz, M.S.Lundstrom (School of Electrical Engng., Purdue Univ., West Lafayette, IN, USA), R.D.Nasby.

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.437-41.

High intensity solar cells which are designed to minimize series resistance and shadowing losses, frequently employ an illuminated surface which is relatively far removed from the collecting junctions. This requires that the surface be well passivated to minimize surface recombination. One technique frequently employed to minimize surface recombination is to incorporate a fixed charge in the passivating oxide. The authors show that at sufficiently high intensities the surface recombination can increase dramatically. This results in a reduction in the high intensity collection efficiency. A comparison of the collection efficiency of interdigitated back contact cells and etched multiple vertical junction cells is given which shows that EMVJ cells are less sensitive to this effect than IBC cells. (4 refs.)

78041 Technology for highly efficient silicon cells for operation above 100 suns. S.Khemthong, F.Ho, P.A.Iles (Applied Solar Energy Corp., City of Industry, CA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.442-7.

In the past year, the efficiency of silicon solar cells has been increased for concentration levels up to 300-suns. Cells with efficiency over 20% at 100-suns, have retained efficiency above 19.5% at 200-suns, and 19% at 300-suns. The design principles and results are presented. (4 refs.)

78042 Some advanced testing techniques for concentrator photovoltaic cells and lenses. J.J.Wiczor, R.J.Chaffin, R.E.Hibray (Sandia Nat. Labs., Albuquerque, NM, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.448-53.

For convenient characterization of concentrator solar cells, the authors have developed a method for measuring the entire illuminated I-V curve of a photovoltaic cell with a single flash of intense simulated sunlight. This method reduces the heat input to the cell and the time required to test a cell, thus making possible quick indoor measurements of photovoltaic conversion efficiency at concentrated illumination levels without the use of elaborate cell mounting fixtures or heat sink attachments. The other test method that they have developed provides a technique to analyze the spatially dependent, spectral distribution of intense sunlight collected and focused by lenses designed for use in photovoltaic concentrator systems. This information is important in the design of multijunction photovoltaic receivers, secondary concentrators, and in optimizing the performance of conventional silicon cell concentrator systems. (6 refs.)

78043 Measurement of concentrator solar cell short-circuit current linearity. R.W.Sanderson, C.E.Backus, J.Birkeland (Coll. of Engng. & Appl. Sci., Arizona State Univ., Tempe, AZ, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.454-8.

The linearity of silicon solar cell short-circuit current with irradiance is investigated using two separate measurement approaches. The first approach involves the measurement of spectral response under concentrated irradiance. The second approach uses neutral density filters to provide a known attenuation to concentrated sunlight, allowing direct measurement of the effect of concentrated sunlight on solar cell short-circuit current. Results indicate a superlinear trend in cell short-circuit current with irradiance, with the greatest deviation from linearity seen for the highest base resistivity cells tested. (5 refs.)

78044 Manufacturing cost analysis of 1980 vintage photovoltaic arrays. T.S.Chan, R.C.Hodge (Advanced Energy Programs Dept., General Electric Co., King of Prussia, PA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.459-62.

Within DOE the photovoltaic concentrator technology project has a technology readiness milestone of substantiating a factory array price of \$2.80/peak watt in a 1980 timeframe. For this timeframe the three most promising concentrator PV approaches are linear focus Fresnel and trough and a point focus Fresnel. Using actual module test data to project annual energy collection potential and detailed manufacturing and installation cost estimates \$/annualized peak watt projections of \$3.50 to \$4.78/watt have been projected. This paper summarizes the work performed to arrive at these cost projections. (5 refs.)

78045 Dispersive concentrating (DISCO) systems based on transmission phase holograms for solar applications. W.H.Bloss, M.Griesinger, E.R.Reinhardt (Inst. fuer Phys. Elektronik, Univ. Stuttgart, Stuttgart, Germany).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.463-8.

The efficiency of photovoltaic generators based on different semiconductor materials with optimized band gaps can achieve considerably higher values than those obtained with single junction solar cells. A new type of a concentrating system is presented which allows high concentration and simultaneously splitting of the spectral region. This dispersive and concentrating (DISCO) system is based on volume phase transmission holograms which exhibit minimum absorption, high diffraction efficiency and adjustable dispersion. The spectral imaging properties of volume phase transmission holograms can be optimized with respect to the requirements for solar applications. An essential tool for this optimization process is the theoretical and numerical description of volume phase holograms. (12 refs.)

78046 Experimental demonstration of the efficacy of global versus direct beam use in performance prediction of flat plate photovoltaic modules. R.D.Whitaker, G.A.Zerlaut, A.W.Purnell (DSET Labs. Inc., Phoenix, AZ, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.469-74.

Accuracy in prediction of module output in the installed configuration is critical to growth of the terrestrial photovoltaics market. Due to momentum from the space application, the United States has tended to retain reliance upon the 'better known' reference spectrum, used in the prediction of photovoltaic output, from the direct beam component at Air Mass 1.5. However, flat plate modules view a hemispherical or global spectrum. Differences have resulted which require resolution. Experiments were performed which show the differences in reference cell calibration constant due solely to the difference in spectrum under which the calibrations were performed. Analysis and experiments demonstrate the ultimate effect of that difference upon I-V curve normalization and resulting power determination. (5 refs.)

78047 Experimental nonidealities in light response and quality factor of photovoltaic diodes. R.R.Potter, J.R.Sites (Dept. of Phys., Colorado State Univ., Fort Collins, CO, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.475-9.

A comparative study has been made of the nature of nonideal behavior in photovoltaic diodes. Several types of solar cells obey the current superposition principle, except for series resistance effects, over a wide temperature range. Other cells, notably lattice mismatched heterojunction cells, show a lack of superposition, interpreted here as an illumination induced reduction in barrier height. All the cells show a large diode quality factor at sufficiently low current densities and generally a fairly sudden transition to a value near one at higher densities. In the better cells this transition occurs many decades below the operating current range; in poorer ones it occurs in or above the operating range directly degrading performance. (4 refs.)

78048 Diffusion length and solar cell efficiency. D.Huber, R.Wahlich, A.Bachmaier (Wacker-Chemitronic, Burghausen, Germany).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.480-4.

The diffusion length of the minority carriers of a solar cell defines the appropriate technology which should be applied for the solar cell fabrication. Back surface techniques only pay off if the diffusion length is long enough. Monocrystalline material with different lifetime killing defects was investi-

gated and an experimental correlation between the diffusion length measured on the unprocessed wafer and the efficiency of the finished cell could be established. (6 refs.)

78049 The flux method applied to excess carrier transport in solar cells. A.M.Buonocristiani, J.Thomchick (Dept. of Phys., Christopher Newport Coll., Newport News, VA, USA). Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.485-9

Describes an alternative theoretical treatment of the transport of excess charge carriers in a solar cell. This analysis avoids the limitations due to the relatively large transport distances inherent in the usual macroscopic device theory. It describes the macroscopic current in terms of microscopic parameters of the semiconductor, for example carrier mobility; the space-charge field effects are treated directly. The results of numerical calculations of the quantum efficiency of a solar cell obtained with this treatment are discussed. (7 refs.)

78050 Generalised boundary conditions for the minority carrier diffusion equation in solar cells. P.T.Landsberg, M.S.Abrahams (Math. Dept., Univ. of Southampton, Southampton, England).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.490-4

For lifetime determinations by photovoltage decay the minority carrier diffusion equation has to be solved. Some results are given of a treatment by Sturm-Liouville transform for the excess minority carrier concentration for decay from a steady state and for the response to a short square light pulse. Carrier profiles and decay data are shown for fairly general time-independent boundary conditions. (6 refs.)

78051 Determination of silicon cell model parameters using a least-squares-fit to experimental spectral response and the V-I curve. G.W.Masden (School of Engng., Walla Walla Coll., College Place, WA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.495-500

An algorithm for the determination of photovoltaic cell parameters and absolute spectral response from terminal V-I measurements is presented. Input consists of V-I curve data measured with the cell operating under full-test illumination, the short circuit current response to superimposed quasi-monochromatic illumination and the spectral distribution of the quasi-monochromatic illumination. The algorithm yields internal spectral response and approximate values for cell model parameters such as minority carrier lifetimes, doping densities, junction depth, recombination velocities, and/or others provided the sensitivity of the cell response to changes in the parameter allows a satisfactory resolution of the parameter. Effects of measurement errors on the computed spectral response and parameters are presented. (3 refs.)

78052 Intensity enhancement in textured optical sheets for solar cells. E.Yablonovitch (Exxon Res. & Engng. Co., Linden, NJ, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.501-6

Describes a statistical mechanical approach for the optics of textured and inhomogeneous optical sheets. As a general rule, the local light intensity in such a medium will tend to be $2n^2(x)$ times greater than the externally incident light intensity, where $n(x)$ is the local index of refraction in the sheet. This enhancement can contribute toward a $4n^2(x)$ increase in the effective absorption of indirect-gap semiconductors like crystalline silicon. Also it may lead to a voltage increase equal to $KT/q 4n^2$. (no refs.)

78053 Maximum power point tracker for photovoltaic power plants. V.Arcidiacono, S.Corsi, L.Lambri (Res. & Dev. Dept., Italian Electricity Board, ENEL, Automatica Res. Center, Milan, Italy).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.507-12

Describes two different closed-loop control criteria for the maximum power point tracking of the voltage-current characteristic of a photovoltaic generator. The two criteria are discussed and compared, inter alia, with regard to the setting-up problems that they pose. Although a detailed analysis is not embarked upon, the paper also provides some quantitative information on the energy advantages obtained by using electronic maximum power point tracking systems, as compared with the situation in which the point of operation of the photovoltaic generator is not controlled at all. Lastly, two high-efficiency MPPT converters for experimental photovoltaic plants of the stand-alone and the grid-interconnected type are presented. (7 refs.)

78054 Estimation of battery charge in photovoltaic systems. J.Appelbaum (Dept. of Electrical Engng., Univ. of Colorado, Boulder, CO, USA), R.Weiss.

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.513-18

The ability to estimate the battery state of charge in an operating system, at any time, is very important from system design point of view. The authors introduce a new on-line method of lead acid battery state of charge determination in a working photovoltaic system. The proposed method is based on the extension of the known open-circuit voltage-charge relation to operating battery voltage-charge relation, combining it with the ampere-hour accounting method for finite periods of time, and averaging out random measurement errors. The method uses electrical measurement of voltage and current at sampling times. The new method was compared experimentally with charge determination methods for a battery at rest (off line methods) and shows good agreement at the control points. The method was developed and validated experimentally for operating conditions which prevail in autonomous photovoltaic systems. (8 refs.)

78055 Inverter characteristics/problems encountered at the Southwest Residential Experiment Station. G.E.Hocking, M.A.Lieberman (New Mexico Solar Energy Inst., Las Cruces, NM, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.519-24

This paper briefly discusses the Southwest Residential Experiment Station (SW RES) experiences with residential-sized, utility-interactive inverters during its first 18 months of operation. The SW RES, operated by the New Mexico Solar Energy Institute (NMSEI) at New Mexico State University, is a test facility established under the National Photovoltaic Program. The experiences with multiple utility-interactive, photovoltaic-powered inverters are summarized, with a specific detailed time line that describes operating versus inactive time. Inverter comparisons encompass DC filters, transformers, night switches, failure mechanisms, and protective features. A discussion of array

configuration and their impact on diagnostics and servicing is included. (no refs.)

78056 The effect of operating-point-control strategy on the annual energy production of degraded photovoltaic arrays. H.M.Branz (Lincoln Lab., MIT, Lexington, MA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.525-31

A new computer simulation of the annual operation of degraded flat-plate photovoltaic (PV) arrays is used to evaluate the need for maximum-power-point tracking in real PV systems. The simulations are based on single-glitch I-V curve shapes rather than particular array degradations, making the data reported applicable to any system whose likely failure modes are predictable and result in single-glitch I-V curves. The simulations show that with a reasonable array wiring strategy, effective maintenance, periodic I-V curve tracing, and avoidance of frequent and serious array shadowing, there is no reason that considerations of degradation should force the adoption of maximum-power-point-tracking power conditioning on a PV system that would otherwise operate economically at fixed voltage. (5 refs.)

78057 A new method of impurity gettering in polycrystalline solar cells. V.Schlosser, F.Kuchar, K.Seeger (Ludwig Boltzmanninst. fur Festkorperphys., Univ. Wien, Wien, Austria).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.532-6

Impurity gettering is a widely used process to improve properties of semiconductor devices. A new method applying a-Si for the gettering in solar cells is reported. Solar cells made on either single crystal or cast polycrystalline substrates, some of them doped with gold were used to show the effect of a-Si as a getter for impurities in the silicon substrate. The a-Si layer is removed by either wet or gas phase etching after the gettering process. As an impurity Au was chosen because it is commonly used for lifetime control in silicon devices. The solar cells are characterized by their minority carrier diffusion lengths L_n and L_p respectively which strongly depend on the number of recombination centers. The diffusion length is determined from spectral response measurements. The spectral response data are fitted to a physical model by means of a least square fit. The results are interpreted as a gettering process of gold impurities by an applied a-Si layer. (6 refs.)

78058 Improved efficiencies of semiconductor and metallurgical grade cast silicon solar cells by hydrogen plasma treatment. W.Schmidt, K.-D.Rasch, K.Roy (AEG-Telefunken, Heilbronn, Germany).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.537-42

Hydrogenation of grain boundaries in multicrystalline silicon solar cells is a promising passivation technique against recombination losses presently under intensified investigation. The improvement of the photovoltaic parameters of hydrogen plasma treated solar cells from large-grain multicrystalline silicon ingots with semiconductor grade (SG) and metallurgical grade (MG) starting silicon is discussed. The change of the photovoltaic parameters distribution, the influence of base resistivity, dopant type, impurity concentration and crystallization technique are analysed. Relative efficiency improvements up to 40% for SG and 85% for upgraded MG solar cells were achieved. (4 refs.)

78059 Grain boundary effects and Li passivation in polycrystalline silicon. F.Kai, G.Rajewaran, M.A.Jackson, V.J.Rao, W.A.Anderson (Dept. of Electrical & Computer Engng., State Univ. of New York, Buffalo, NY, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.543-7

A relatively new technique for Li passivation has been used to reduce the active grain boundary effects in poly-Si. The Li passivated cells have generally shown better photovoltaic data, higher spectral response and smaller ideality factor in dark and light I-V than both etched and annealed cells. The interface state density of the passivated cell is lower than for the non-passivated cells. Ion probe data shows Li to diffuse three orders more rapidly in the grain boundary than in the solid silicon. (15 refs.)

78060 The measurement of variations in minority carrier lifetime due to microstructural defects in large area polysilicon wafers. S.M.Johnson, J.S.Culik (Solarex Corp., Rockville, MD, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.548-53

Describes the measurement and analysis of minority carrier lifetime inhomogeneities in large area polysilicon wafers used to fabricate solar cells. Variations in free carrier lifetime are measured using a contactless microwave technique. The use of a subsequent Secco etch enables structurally related minority carrier lifetime degradation mechanisms to be distinguished from impurity related lifetime decreases. (19 refs.)

78061 Enhanced diffusion of phosphorus at grain boundaries [Si solar cells]. L.J.Cheng, C.M.Shyu, K.M.Stika, T.Daud, G.T.Crotty (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.554-8

Enhanced diffusion of phosphorus at grain boundaries in cast polycrystalline photovoltaic materials (Wacker, HEM, and Semix) was studied. It was found that the enhancements for the three materials were the same, indicating that the properties of boundaries are similar, even though they were grown by different techniques. In addition, it was observed that grain boundaries capable of enhancing the diffusion always have strong recombination activities. Both phenomena could be related to dangling bonds existing at the boundaries. The present study gives the first evidence that incoherent second order twins of {111}/{111} type are diffusion-active. (9 refs.)

78062 Bifacial cells of p^+in^+ structure. G.L.Araujo (Inst. de Energia Solar, Univ. Politecnica de Madrid, Madrid, Spain), A.Luque, E.Sanchez, M.J.Calleja, S.Lopez Romero, J.Castano.

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.559-64

Bifacial cells of p^+in^+ structure are intrinsically very symmetric as shown both, theoretically and experimentally. Their bifacial behaviour is analyzed and compared to that of p^+nn^+ cells in low injection for low values of the diffusion length. Cells of p^+in^+ structure are anticipated to present better bifacial behaviour for all the ranges of L. An approximate two-exponential formula is given to account for the behaviour of p^+in^+ cells and the values of the parameters in this formula are measured in typical cases. The validity of superposition is studied, leading to the conclusion that it is not theoretically satisfied. The results of a pilot fabrication of p^+in^+ bifacial cells are given and compared to those of low injection bifacial cells. (8 refs.)

78063 On the effective minority carrier diffusion length of polycrystalline silicon solar cells. S.Kumari, S.K.Jain, B.K.Das, G.C.Jain (Nat. Phys. Lab., New Delhi, India).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.565-8

Polycrystalline substrates can be characterized in terms of an 'effective' minority carrier diffusion length, L_e . Based on a generalised expression, L_e has been computed for polycrystalline Si solar cells in terms of the intragrain diffusion length L_g , grain size d and the distance λ to which the grain boundary has an influence βL_g , in accordance with a model suggested by Koliwad and Daud (1980). They have demonstrated $\beta=1$. These theoretical computations have been compared with the experimental results of diffusion length measurements on solar cells fabricated out of solar grade polysilicon. The value of β has been found to vary randomly between 1.3 to 1.7 assuming uniform L_g in all the grains. This is thought to be due to impurity induced effects. Non uniform grain boundary enrichment of impurities like Fe, Cr, Ni and Cu has been observed using SAM and SIMS techniques. (6 refs.)

78064 Fabrication process and performances of a new type of GaAs-GaAlAs cascade solar cell. C.Flores (CISE SpA, Milano, Italy).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.569-73

A novel cascade solar cell with two junctions and three terminals, has been fabricated. The cell consists of a GaAs P-N junction covered with a $Ga_{0.8}Al_{0.2}As$ N-P junction. This structure has been realized using a process that involves a minimum number of epitaxial layers and an easy fabrication process. The cell has been tested at different sun concentrations. The conversion efficiency is 20.5% at 80 suns and decreases to 16.2% at 500 suns. (7 refs.)

78065 The V-groove silicon solar cell. P.G.Borden, R.Walsh (Varian Associates, Palo Alto, CA, USA), R.D.Nasby.

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.574-7

The V-groove silicon solar cell is designed to achieve high efficiency at high concentration. It uses a V-groove front surface to obtain minimal grid shadowing losses, while allowing high fractional grid coverage. The serrated structure and front surface refraction minimizes the photon penetration depth, reducing the required diffusion length and allowing use of epitaxial layers on highly doped substrates. This minimizes base resistance. Cells have achieved 17.4% AM1 efficiency at 200 suns, 24°C, with 25% front grid coverage. (10 refs.)

78066 Reduction of open circuit voltage in solar cells at very high illumination intensity. J.E.Parrott, H.R.A.Beddie (Dept. of Phys., Electronics & Electrical Engng., Univ. of Wales Inst. of Sci. & Technol., Cardiff, Wales).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.578-83

Examines the behaviour of GaAs and Si solar cells over a range of illumination intensities up to about 10^5 W/cm². Photovoltage saturation as described by Parrott and others (1974, 1976) was apparently not observed due to the appearance of an effect causing a voltage decrease at the higher illumination levels. Experimental results for a few cells are shown and the various possible mechanisms for this effect are discussed. (7 refs.)

78067 Superlattice cascade solar cell. M.W.Wanlass, A.E.Blakeslee (Solar Energy Res. Inst., Golden, CO, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.584-9

Reports progress toward realization of a new cascade solar cell structure whose chief advantages over other present concepts are: use of silicon for the substrate and low bandgap cell; avoidance of the necessity of lattice matching; and incorporation of a GaAs/GaP superlattice to enhance efficiency and provide a low-resistance connecting junction. Details of the design and operation of an OMCVD system from growing this structure are presented. Results of experiments to optimize layer thickness, compositional uniformity, and surface morphology are described. (17 refs.)

78068 A four-cell photovoltaic system based on InP and GaAs. B.Beaumont, G.Nataf, F.Raymond, C.Verie (Lab. Phys. du Solide et Energie Solaire, Valbonne, France).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.595-600

A four-bandgap photovoltaic system is proposed. It combines two monolithic stacked two-bandgap solar cells coupled through a dichroic mirror. Detailed modelling studies together with a discussion on the choice of semiconductor materials for the photovoltaic cells are described. The projected operating efficiency is shown to be above 35%, reaching a value as high as 42% in the case of the four-cell converter. Experiments are under progress. (11 refs.)

78069 Grain boundary structure and properties in polycrystalline silicon. Y.S.Tsuo, R.W.Hardy, J.B.Milstein (Solar Electric Conversion Res. Div., Solar Energy Res. Inst., Golden, CO, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.610-21

Reviews recent advances in studying the grain boundary properties of polycrystalline silicon solar cell materials are reviewed. Of particular importance are the recent improvements in hydrogen grain boundary passivation techniques that have not only shortened the required passivation treatment time to only a few minutes but also demonstrated the ability to significantly increase polycrystalline silicon solar cell efficiencies for both large-grained and small-grained materials. (36 refs.)

78070 Grain boundaries in silicon solar cells. L.L.Kazmerski, P.E.Russell, P.J.Ireland, C.R.Herrington, J.R.Dick, R.J.Matson, K.M.Jones (Solar Energy Res. Inst., Golden, CO, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.622-6

The correlations between the electrical and compositional properties of grain boundaries in polycrystalline Si are examined in detail. High-resolution surface analysis techniques (AES, SIMS, XPS, EELS) and microelectrical (SAM, EBIC, minority-carrier lifetime) characterization methods are used. The direct evidence for impurity segregation to the intergrain regions is presented. Effect of illumination on the grain boundary electrical characteristics are correlated with impurity compositions. Finally, the interrelationships among heat-treatment, oxygen segregation and grain boundary electrical activity are discussed. (24 refs.)

78071 Evaluation of EBIC images at grain boundaries. J.Marek (Max-Planck-Inst. fur Festkörperforschung, Stuttgart, Germany).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.627-32

A physically appropriate model for EBIC images in polycrystalline semiconductors is developed. EBIC signals are calculated for a set of parameters ranging from 1 to 200 μ m for the diffusion length of the grain and 5 to 60 keV for the electron beam energy. Experiments on large-grain Si solar cells are performed and compared with theory. The experimental and calculated profiles agree within 2%. The analysis of the profile allows determination of the diffusion length in the grain and of the grain boundary recombination velocity. (13 refs.)

78072 Carrier transport at grain boundaries in silicon. H.C.Card, J.G.Shaw, G.C.McGonigal, D.J.Thomson, A.W.de Groot, K.C.Kao (Dept. of Electrical Engng., Univ. of Manitoba, Winnipeg, Manitoba, Canada).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.633-9

A series of experimental measurements is presented of electron and hole transport at grain boundaries (and dislocations) in cast silicon. These experiments include four-probe measurements on individual grain boundaries, the effects of grain-boundary proximity on Schottky barrier characteristics and spectral/photovoltaic behaviour of 1 cm² grating solar cells (both minMIS and majority-carrier types). In addition, the results of theoretical studies are described, which employ numerical finite-element methods with the Newton-Raphson-Kantorovich algorithms. In these calculations, the quasi-Fermi potentials and the electrostatic potential across the grain boundary are solved self-consistently, without the need for a priori assumptions of particular carrier transport mechanisms. (24 refs.)

78073 Grain boundary effects in polycrystalline silicon solar cells. N.C.Halder (Dept. of Phys., Univ. of South Florida, Tampa, FL, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.640-3

By solving the three-dimensional diffusion equation by Green's function method, the I-V characteristics of polycrystalline Si solar cells with vertical grain boundaries and n-p junctions have been investigated. The procedure includes the effects of grain size, thickness of the cell and the recombination velocity of the minority carriers at the grain boundary. The results of this study suggest that an efficiency as high as 15% may be achieved with samples of grain size 100 μ m, thickness 100 μ m, and velocity 100 m/sec when other loss mechanisms are negligibly small or absent. (8 refs.)

78074 Design principles for high efficiency small-grain polysilicon solar cells, with supporting experimental studies. F.A.Lindholm (Univ. of Florida, Gainesville, FL, USA), A.Neugroschel, C.T.Sah.

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.644-7

Design principles suggested here aim toward high conversion efficiency (>15%) in polysilicon cells. The principles seek to increase the liabilities of both intragrain and grain-boundary-surface defects. The advantages of a phosphorus atom concentration gradient in a thin (≤ 50 μ m) base of a $p^+/n(x)/n^+$ drift-field solar cell, which produces favorable gradients in chemical potential, minority-carrier mobility and diffusivity, and recombination lifetime (via phosphorus gettering). The degrading effects of grain boundaries are reduced by these three gradients and by substituting atoms (P, H, F or Li) for vacancies on the grain-boundary surface. From recent experiments comes support for the benefits of P diffusion down grain boundaries and for quasi-grain-boundary-free and related structures. New analytic solutions for the $n(x)$ -base include the effect of a power-law dependence between P concentration and lifetime. These provide an upper-bound estimate on the open-circuit voltage. Finite-difference numerical solutions of the Shockley equations furnish complete information about all solar-cell parameters and add insight concerning design. (25 refs.)

78075 Theoretical and experimental studies of tandem or cascade solar cells: a review. J.J.Loferski (Brown Univ., Providence, RI, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.648-54

Discusses the principles underlying the fabrication of high efficiency solar cells of the tandem or cascade type. Such a PV cell system consists of a number of individual cells in which the photovoltaically active semiconductors (PVAS) have different bandgaps selected in accordance with certain rules. The author describes the 'unit cell' for such a cascade system; the unit cell incorporates minority carrier mirrors to optimize its performance. Identification of semiconductors having energy gaps in the range 1.0 eV to 2.0 eV for the cascade cells is discussed. It is shown that semiconductor alloys must be used for the PVAS. A few potential alloy systems are examined and it is shown that satisfying all the requirements for PVAS in cascade systems results in a very limited number of suitable systems. A brief discussion of the status of experimental work aimed at realization of these PVAS and tandem cells is also included. (15 refs.)

78076 Ternary III-V solar cells for multicolor applications. L.M.Fraas, B.K.Shin, J.A.Cape, R.A.Ransom, D.E.Sawyer (Chevron Res. Co., Richmond, CA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.655-62

High efficiency, shallow-junction GaAs(1-x)P(x) and GaAs(1-y)Sb(y) ternary III-V solar cells are reported for the first time. The authors report a GaAs(0.82)P(0.18) cell with a band gap of 1.65 eV and an energy conversion efficiency of 14.8% at 7.4 suns and a GaAs(0.88)Sb(0.12) cell with a band gap of 1.2 eV and a conversion efficiency of 15.6% at 18 suns. Both cells were fabricated on GaAs substrates. These cells were then used as the building blocks for multicolor solar cells. Both two-dimensional and three-terminal, two-color cells were fabricated. The two-terminal devices used a p^+/n GaAs-shorting junction to series connect a GaAs(1-x)P(x) n^+/p visible light-sensing junction to a GaAs(1-y)Sb(y) n^+/p infrared-sensing junction. The expected voltage addition was demonstrated. The three-terminal devices were transistor-like devices in which an n^+/p GaAs(1-x)P(x) cell was grown on a p^+/n GaAs(1-y)Sb(y) cell. The third terminal was attached via etched-in grooves to the GaAs(1-x)P(x) p-layer. The three-terminal device allows independent testing of both active junctions in a monolithic two-color stack. Both junctions in these three terminal devices performed qualitatively as expected. (11 refs.)

78077 Recent developments for the AlGaAsSb cell. M.L.Timmons (Research Triangle Inst., Research Triangle Park, NC, USA), S.M.Bedair, R.J.Markunas, J.A.Hutchby. Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.663-8

Improvements in open circuit voltage of the individual components of two junction, monolithic solar cells in the Al-Ga-As-Sb material system are reported. These improvements have accompanied reductions in dislocation densities which have been obtained since changing from (111)A- to (100)-oriented GaAs as the growth substrate. Limits of defect reduction by conventional LPE are being approached, and therefore, further significant device improvements seem unlikely. Hybrid growth using both OMCDV and LPE and growth of superlattice structures are described. These approaches probably have the best chance of solving the remaining defect problem and permitting evaluation of the AlGaAsSb cell's ability to attain the voltages of the cascade model. (10 refs.)

78078 Test data analysis and results for concentrating photovoltaic modules. M.W.Edenburn, H.J.Gerwin, C.J.Chiang (Sandia Nat. Labs., Albuquerque, NM, USA). Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.669-74

Presents an expression for efficiency that is a linear function of cell temperature and illumination. This expression is used to correlate test data for concentrating photovoltaic modules. The linear form of the equation is justified by showing that it derives from a cell model that considers the cell to be a parallel current source and diode in series with a resistance. The linear expression has been used to correlate test results for a variety of concentrating modules. Results for those modules that are currently the most promising and interesting to the photovoltaic community are presented in the paper. (4 refs.)

78079 A passive cooled 1000X GaAs module with secondary optics. N.Kaminar, P.Borden, M.Grounner, P.Gregory, R.LaRue (Varian Associates Inc., Palo Alto, CA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.675-8
Describes a new module design using 36 GaAs cells running at 1000:1 concentration ratio with passive cooling. The unique optical system uses flat Fresnel lenses and solid glass secondary concentrators to improve on- and off-track performance. Over 18% module efficiency and $\pm 0.8^\circ$ allowable tracking error have been obtained in tests of this optical system. (no refs.)

78080 Design parameters of high efficiency a-SiC:H/a-Si:H heterojunction solar cells. Y.Hamakawa (Faculty of Engng. Sci., Osaka Univ., Osaka, Japan), Y.Tawada, K.Nishimura, K.Tsuge, M.Kondo, K.Fujimoto, S.Nonomura, H.Okamoto.

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.679-84
Design concept and a series of technical data on the a-SiC:H/a-Si:H heterojunction solar cell having conversion efficiency of 8.8% are demonstrated. The cell has a wide band gap window heterojunction layer made of hydrogenated amorphous silicon carbide (a-SiC:H) with a proper valency control. A series of basic properties of the hydrogenated a-SiC:H films are presented. Device physics considerations and optimizations of design parameters for heterojunction solar cells with this new material are demonstrated. Remarkable improvements in cell performances have been attained employing the a-SiC:H window junction. A brief discussion is given on the realistic limit of the conversion efficiency in this type cell. (29 refs.)

78081 Prospects of II-VI based solar cells. S.Wagner (Dept. of Electrical Engng. & Computer Sci., Princeton Univ., Princeton, NJ, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.685-91
Three out of the four thin film cells that have reached an efficiency of 10% are based on II-VI semiconductors. Does this success in the laboratory forebode a commercial II-VI technology? In an attempt to answer this question the author reviews the applications which the II-VIs have found as windows and as absorbers. He concludes with a discussion of the principal cells, $\text{Cu}_2\text{S}/(\text{Zn,Cd})\text{S}$, $\text{CuInSe}_2/(\text{Zn,Cd})\text{S}$ and CdTe/CdS in the light of a list of empirical criteria for a large scale technology. (21 refs.)

78082 Optimal design of high-efficiency tandem cells. J.C.C.Fan, B.-Y.Tsaur, B.J.Palm (Lincoln Lab., MIT, Lexington, MA, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.692-701
Computer analysis indicates that a substantial increase in solar cell conversion efficiencies can be achieved by using two-cell, multibandgap tandem structures instead of single-junction cells. Practical AM1 efficiencies of about 30% at one sun and over 30% at multiple suns are to be expected. The further increases in efficiency calculated for a three-cell tandem structure are much smaller and may not justify the added complexity. For inexpensive two-cell tandem modules, Si is preferred for the bottom cell, and the top-cell material should have a bandgap of 1.75 to 1.80 eV. The GaAs-AlAs and GaAs-GaP systems are very attractive candidates for the top cell. Significant advances have been achieved in growing GaAs on Ge-coated Si substrates (for the two-terminal, two-cell structure) and in growing free-standing ultrathin GaAs layers (for the two-terminal or four-terminal structures). These advances should be transferable to the GaAs-AlAs and GaAs-GaP systems. (22 refs.)

78083 Photovoltaic concentrator progress. E.C.Boes (Sandia Nat. Labs., Albuquerque, NM, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.702-12
Gives a brief but comprehensive summary of the status of photovoltaic concentrator technology. It includes a discussion of various concentrator concepts; a report on the experiences of 6 experimental PV concentrator array fields; test results on more recent PV concentrator module designs; a discussion of data analysis tools; new results on concentrator component development; a discussion of the solar resource differences for flat plate and concentrating collectors; and a discussion of cost analyses and price targets for this technology. (19 refs.)

78084 Final results on the development of high efficient, stable Cu_2S -CdS thin film solar cells. G.H.Hewig, F.Pfisterer, H.W.Schock, W.Arndt, W.H.Bloss (Inst. fuer Phys. Elektronik, Univ. Stuttgart, Stuttgart, Germany).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.713-18
A procedure for the production of stable Cu_2S -CdS thin film solar cells and modules is described. Diagnostic methods applied in order to optimize the production parameters and the respective material properties of high efficiency cells are summarized. Possible degradation mechanisms are outlined and ways to avoid them are discussed. Large area cells (42 cm^2) show efficiencies up to 8% at AM 1.5. Results of outdoor tests are reported indicating no measurable degradation after more than three years operation with maximum power load. (8 refs.)

78085 Stability of thin-film Cu_2S -based solar cells at V_{oc} under continuous illumination. J.E.Phillips, R.W.Birkmire, P.G.Lasswell (Inst. of Energy Conversion, Univ. of Delaware, Newark, DE, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.719-22
Thin-film Cu_2S -based solar cells have been developed which are free of the shunting defects that cause the electrochemical decomposition of the Cu_2S . These cells have been held at open-circuit voltage under continuous illumination in an inert or reducing atmosphere for over 500 hours with no degradation in efficiency, short-circuit current, or open-circuit voltage. Laser scanning techniques have been developed as a tool for detecting cell defects and recently, these techniques have been used to locate shunting defects in ungridded Cu_2S -based cells. By using the laser scanner, it has been possible to detect and eliminate defects that cause electrochemical decomposition of the Cu_2S . (11 refs.)

78086 A study of the stability of cadmium sulfide/copper sulfide solar cells. G.T.Noel, G.B.Gaines, N.A.Richard (Battelle Columbus Labs., Columbus, OH, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.723-30

The results of an experimental study of the intrinsic degradation mechanisms in cadmium sulfide/copper sulfide solar cells are reported. Behavior during degradation of both voltage and current is described. No major trend of fill factor degradation was observed for the primary cells used in this study, although significant degradation of this parameter has been observed in other cell types. The voltage degradation can be recovered by 'resting' or reverse biasing the cells, while recovery of the degradation of the light generated current requires reirradiation. Statistical summaries of degradation data, including degradation rates, for cell groups exposed to combinations of stresses (temperature, load, illumination, roof-top ambient) are presented. These indicate that open-circuit is the most stressful load condition. Possible mechanisms and causative factors for the observed degradation modes are discussed. Preliminary results of a study of the stability of cadmium sulfide/copper-indium selenide photovoltaic devices are also presented. (14 refs.)

78087 Development of spectral response ratios as a diagnostic tool for $\text{Cu}_2\text{S}/\text{CdS}$ thin film cells. L.A.Brickman, J.A.Bragagnolo, H.R.Zwicker (Thin Film Div., Solvovolt Internat., Newark, DE, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.731-6

Ratios of pairs of spectral response curves for $\text{Cu}_2\text{S}/\text{CdS}$ thin-film solar cells are shown to exhibit highly sensitive spectral shapes which are characteristic of certain process variations or degradation modes. These shapes can be related to variations in specific parameters in a theoretical quantum efficiency model which describes both photon and electron losses in the device. This 'ratio technique' is used as a non-destructive diagnostic tool for light-generated current losses in $\text{Cu}_2\text{S}/\text{CdS}$ cells. (11 refs.)

78088 Copper sulfide/cadmium sulfide heterojunction cell research by sputter deposition. J.A.Thornton (Telic Co., Santa Monica, CA, USA), D.G.Cornog, W.W.Anderson, R.B.Hall, J.E.Phillips.

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.737-42

Reports on an investigation concerning the use of magnetron reactive sputtering for fabricating $\text{Cu}_2\text{S}/\text{CdS}$ solar cells. Hybrid cells have been fabricated which combine reactive sputtered Cu_2S with evaporated CdS and (CdZn)S layers. A $\text{Cu}_2\text{S}/(\text{CdZn})\text{S}$ (14 at.% Zn) cell of this type, with an evaporated Ta_2O_5 antireflection layer, has yielded: $J_{sc}=18.5 \text{ mA/cm}^2$, $V_{oc}=0.53 \text{ V}$, $\text{FF}=0.72$ and $\eta=7.20\%$. All-sputtered planar thin film $\text{Cu}_2\text{S}/\text{CdS}$ cells have been deposited onto glass substrates, without breaking vacuum, using a multi-source deposition apparatus. A cell of this type without an antireflection coating has yielded: $J_{sc}=12.2 \text{ mA/cm}^2$, $V_{oc}=0.53 \text{ V}$, $\text{FF}=0.62$ and $\eta=3.94\%$. (17 refs.)

78089 Hydrogen pretreatment of CdS films and properties of CdS/NaOH/Pt cells. C.D.Lokhande, M.D.Uplane, S.H.Pawar (Dept. of Phys., Shivaji Univ., Kolhapur, India). *Indian J. Pure & Appl. Phys.*, vol.21, no.2, p.78-81 (Feb. 1983). Cadmium sulphide films have been deposited on both glass and stainless steel substrates by chemical bath deposition technique. The post-preparation heat treatment in hydrogen atmosphere is given to the films and CdS/NaOH/Pt cells are formed. The influence of hydrogen treatment to CdS film electrode on the electrical and optical properties of these cells is studied. The variation of I_{sc} and V_{oc} is explained as due to the diffusion of sulphur vacancies and due to the increase in crystallinity in the CdS film both being caused by the heat treatment. (17 refs.)

78090 Development and evaluation of the Texas Instruments Solar Energy System. W.R.McKee, K.R.Carson, J.D.Levine (Texas Instruments Inc., Dallas, TX, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.257-62

The Texas Instruments Solar Energy System (TISES) is a unique solar energy conversion and storage system with many potential cost advantages over other approaches now being considered. The individual photovoltaic elements are tiny silicon spheres which are packed into thin glass sheets and then immersed in an HBr electrolyte where they perform an electrolysis function. The system provides for storage of the reaction products and then recombination in a fuel cell to produce an electrical output. The development status of the various system components are presented. Plans for outdoor testing of a complete, functional prototype unit are discussed. (5 refs.)

86.30Q Chemical energy conversion

(for electrochemical conversion, see 86.30D; for photoelectrochemical conversion, see 86.30K)

78091 Transfer and storage of chemical and radiation potential. G.Porter (Davy Faraday Res. Lab., Royal Inst., London, England). *J. Chem. Soc. Faraday Trans. II (GB)*, vol.79, pt.3, p.473-82 (March 1983). The change in potential which accompanies any spontaneous process is given by $RT \ln[1 - (j/J)]$, where j is the net forward flux and J is the forward flux at the same reactant potential but in the absence of products. This equation is applied to thermal and photochemical reactions. For the latter, the author introduces and evaluates the quantities 'radiation potential' and 'scattered radiation potential' in analogy with 'chemical potential'. 'Storage' of energy is defined and shown to be a two-stage process. Thermodynamic losses are relatively small provided the rather stringent requirements of geometry and transport kinetics can be met. The influences of these several factors on the efficiency of solar-energy collection and storage are evaluated. (12 refs.)

86.30S Photothermal conversion

78092 Flow distribution in parallel connected manifolds for evacuated tubular solar collectors. R.C.McPhedran, D.J.M.Mackey, D.R.McKenzie, R.E.Collins (School of Phys., Univ. of Sydney, Sydney, NSW, Australia). *Aust. J. Phys. (Australia)*, vol.36, no.2, p.197-219 (1983).

A model is presented for predicting the flow distribution in solar collector manifolds in which risers are connected in parallel between headers. Both frictional and Bernoulli effects are considered. The distributions resulting from flow in the manifold in which header streams are parallel and opposed are calculated and compared with experiment. Parallel flow gives a more uniform distribution. The outlet header is found to be more critical in balancing the flow distribution than the inlet header. Conditions under which thermosiphon effects are important and flow reversal in risers may occur are discussed with reference to experiment. (10 refs.)

78093 F-chart method applied to large-scale solar collector systems subject to a shadow effect of adjacent collectors. M.Schroeder (Vereinigte Deutsche Metallwerke AG, Frankfurt, Germany). *Int. J. Sol. Energy (Switzerland)*, vol.1, no.3, p.169-84 (1982).

The specific example of a 400-bed hotel is investigated to determine how the shadow effect due to adjacent collectors, arising through a limited roof area, is reflected in the behaviour of the annual f as a function of the collector surface. The study is performed for two different locations of the hotel, Almeria, Spain, and Freiburg, Germany, which reveals the dependence of the latitude on the shadow effect. It is illustrated that the effect of shading is substantially affected by the monthly distribution of the occupation of the hotel. The optimal collector surface in the presence of the shadow effect is then determined from economic aspects by seeking the surface yielding the maximum life-cycle savings. (8 refs.)

78094 Radiation heat exchange in a solar cavity-type receiver at various times. K.Spindler, U.Gross, E.Hahne (Inst. fur Thermodynamik und Warmetech., Univ. Stuttgart, Stuttgart, Germany). *Int. J. Sol. Energy (Switzerland)*, vol.1, no.3, p.197-212 (1982).

Steady-state solar and infrared radiation heat exchange in the cavity receiver of a solar tower is presented in the form of a mathematical model. The inside cavity walls consist partly of tubes containing air as a heat carrier. The distribution of tube wall temperatures, air temperature, and the heat flux density along the tubes are calculated at different times of day for different seasons. The efficiency of solar and infrared radiation exchange in the cavity is determined, as well as cosine losses of the heliostate field. The receiver layout is based on maximum gain on 21 June, 12 o'clock noon. (3 refs.)

78095 Present state and development of solar techniques. D.Teodorescu. *Elektr. Masch. (Germany)*, vol.62, no.2, p.43-8 (Feb. 1983). In German. Discusses the production of temperatures above 300°C by solar energy devices for power production. Several solar heat absorbers capable of meeting such power requirements are described. Heat transfer is up by a flow of liquid or gas. Particular attention is paid to the lagging. A revolving sun ray collector incorporating focusing mirrors is described. Other developments and applications dealt with are Stirling cycle solar motors and solar cells. (31 refs.) G.R.S.

78096 A simplified theory for a matrix solar collector. D.Singh, N.K.Bansal (Indian Inst. of Technol., Hauz Khas, New Delhi, India). *Int. J. Energy Res. (GB)*, vol.7, no.2, p.173-7 (April-June 1983).

Presents a simple generalized analysis for a matrix collector and obtains closed form solutions for the equations. Numerical calculations are performed corresponding to the experimental data of Chau and Henderson. (3 refs.)

78097 Performance of n forced circulation water heating systems in series. M.S.Sodha, V.S.V.Bapeshwara Rao, G.N.Tiwari (Indian Inst. of Technol., New Delhi, India). *Int. J. Energy Res. (GB)*, vol.7, no.2, p.179-86 (April-June 1983).

Presents an analytical investigation of the thermal performance of a forced circulation solar water heating system in which n water heating systems are connected in series. Numerical calculations have been made for a typical cold day (26 January 1980) in Delhi, India, and some interesting conclusions have been presented. (15 refs.)

78098 A dynamic simulation of a flat-plate collector system. A.Annino (Istituto di Fisica, Facolta di Ingegneria, Catania, Italy). *Nuovo Cimento B (Italy)*, vol.74B, ser.2, no.2, p.139-50 (11 April 1983).

Starting with the energy balance analysis of a solar flat-plate collector, a model has been developed to simulate the system's behaviour. The model uses the state equation formalism which permits an easy simulation by minicomputer (Olivetti P6060). The experimental tests performed show that the model describes well the energy output, the spatial distribution and the time dependence of temperature in various elements. (12 refs.)

78099 Ge-Al thin films for selective solar absorbers. F.R.Kessler, K.Dettmer, E.-W.Ritters (Inst. fur Halbleiterphys. und Optik, Tech. Univ. Braunschweig, Braunschweig, Germany). *Phys. Status Solidi A (Germany)*, vol.76, no.2, p.533-41 (16 April 1983).

Ge-Al thin films prepared by simultaneous evaporation in high vacuum show plasma resonance adjustable between 1 and 3 μm . The relatively sharp change from high reflectivity at $\lambda < \lambda_r$ to low reflectivity in connection with negligible transparency at $\lambda < \lambda_r$ make them suitable for selective solar absorbers especially at high working temperatures between 50 and 250°C. The selectivity is about 25. Under AM 1 illumination and thermal isolation a stationary steady-state temperature of 280°C is reached. This value is valid in the case of an additive antireflection coating adjusted for $\lambda = 0.55 \mu\text{m}$. The static and dynamic characteristics are given. The very high degree of degeneracy of the p-type overdoped germanium thin films is characterised by the position of the Fermi level inside the valence band down to 0.7 eV. The resulting optical properties of the thin films are discussed. Thermoreflection measurements especially indicate the failure of the E_0' and $E_0' + \Delta_0$ interband transitions near 3.2 eV. (9 refs.)

78100 Effects of a solar reflecting film on the reduction of solar heat gain through fenestration. Y.Urano, A.Hoyano, Y.Shiotsuki, S.Chirifu, Y.Kumagawa. *Technol. Rep. Kyushu Univ. (Japan)*, vol.55, no.6, p.657-65 (Dec. 1982). In Japanese. [received: May 1983]

Control of solar heat gain through fenestration has been considered to be of increasing importance as a result of the great use of glass in buildings. The effects of a solar reflecting film attached on the inner surface of window panes on the thermal environment of a room were investigated. The measurements were carried out in an existing building in which 75% of the facade area was covered with glass and which had no concavities. The components of solar heat gain were calculated and the solar heat gain factors of the reflecting film were obtained. The use of the reflecting film with 17% solar transmittance reduces the solar heat gain by 25 to 55% as compared with the conditions without the film, and the use of it improves the thermal environment at the perimeter zone of the room. (7 refs.)

78101 Entwicklung von autarken Solarkuhlanlagen mit konzentrierenden Kollektoren (Development of self-sufficient solar cooling devices with concentrating collectors). H.Simon. *Report EUR 8165 DE*, Comm. European Communities, Luxembourg (1982), 35 pp. In German. Contract ESA/C/043/D.

Tests are reported on an ammonia-water-absorption cooling machine of about 10 kW capacity (with electrical collector simulation) to observe its performance and efficiency. Two modes of coupling of the collector and the absorption cooling unit were tried out and compared; the direct coupling enabled good system control. The achieved efficiency of the system was about 20% below the predicted one. By reducing the air heat exchanger rating to half the system could be successfully used for air conditioning. Data of the two systems are tabulated and results of tests carried out in summer and winter in various geographical locations are shown.

78102 Weathering performance of cover materials for flat plate solar collectors. E.J.Clark, W.E.Roberts. *Report NBS-TN-1170*, Nat. Bur. Stand., Washington, DC, USA (Nov. 1982), x+69 pp.

Weathering studies were performed to obtain data on the performance and durability of cover plate materials for flat plate solar collectors used in solar heating and cooling systems. Ten materials were evaluated to assess their durability after natural weathering and artificial weathering with a xenon arc light. The materials were weathered for four years on small minicollectors in Arizona, Florida, and Maryland after which the solar energy transmittance and the effect of dirt on the transmittance were measured. The tensile properties of selected film materials were also assessed after weathering. The effects of the natural weathering are compared: (1) for materials exposed as inner and outer cover plates for each weathering site; (2) for the three weathering sites; and (3) with materials artificially weathered with a xenon arc light. (19 refs.)

78103 Design and construction of a hybrid photovoltaic (3 kW_{th})-thermal solar energy system for a residential/commercial building. J.J.Loferski, C.Case, G.Doodesack, B.Roessler, R.Dobbins, T.Russell, J.Beall, J.Krikorian (Div. of Engng., Brown Univ., Providence, RI, USA).

Conference Record of the Sixteenth IEEE Photovoltaic Specialists Conference - 1982, San Diego, CA, USA, 27-30 Sept. 1982 (New York, USA: IEEE 1982), p.188-93

Describes the planning, design and construction of a flat plate hybrid photovoltaic/thermal system with an electric heat pump intended for on-site generation of heat and electricity for a dwelling or commercial building. The twenty PV/T collectors have 3'x6' absorber surfaces and incorporate approximately 3000 four inch diameter silicon cells bonded to glass with a high-temperature-tolerant, UV-degradation-resistant silicone bonding cement. Extensive computer modelling of the system has shown that about 65% of the total annual energy needs (heating, cooling, hot water, distributed electric load) will be provided by the PV/T system. Half of this energy will be electrical; half, thermal. Coupling with the utility is through a synchronous inverter. The system can store thermal energy for space heating in a rock bin storage box. Results of an economic analysis are also included. (4 refs.)

| 78104 The importance of biomass peak power plants in power industry. M.Vronsky. <i>Energetika (Czechoslovakia)</i> , vol.33, no.3, p.114-16 (1983). In Slovak. The concept of biomass conversion based on a dry fermenting process is described. It is pointed out that investment costs for power plants based on this process are relatively low and that even small plants which can be situated near the sources of biological waste materials can become feasible. Drive motors suitable for biomass converting plants are briefly dealt with. It is pointed out that costs savings can be achieved by using some by-products of the conversion process (fertilizers). The potential of the conversion process in Czechoslovakia is assessed. (4 refs.) E.D. |

| 78105 Seasonal thermal inventory. C.I.Staicu, C.Bilegan, A.Mihaila, A.Predica. <i>Energetica (Romania)</i> , vol.31, no.1, p.35-9 (Jan. 1983). In Rumanian. The present all-over seasonal thermal inventory stage is presented and the solutions applied for the heat storage are described briefly. Technical data for practical seasonal thermal inventories are given. Referring to the theoretical study of the thermal storage it is shown that the equations describing hydrodynamic and transfer processes are solved by the method of finite elements by computer. Finally, the main problems which determine the seasonal thermal storage are outlined. (7 refs.) | |

86.40K Hydrogen storage and technology

| | |
|--|-----------------|
| 78106 Theoretical and experimental aspects of a two-step short cycle, based on ZnO and CdO intended for storage of solar energy. M.Comtat (Lab. de Chimie-Phys. et d'Electrochimie, Univ Paul-Sabatier, Toulouse, France), M.Ducarroir, F.Sibieude, G.Crozat, B.Spinner. <i>Int. J. Energy Res. (GB)</i> , vol.7, no.2, p.137-53 (April-June 1983). Chemical and energetical considerations about hybrid thermal electrochemical cycles based on zinc and cadmium oxides are developed. Intermediate reactions have been taken into account. Numerical data obtained from decomposition experiments of the oxides in a solar furnace and from electrolysis experiments with Zn and Cd metals (or metal-oxide mixtures) used as an anode, are discussed. The energy balance for the hydrogen production using the mentioned cycles is compared with a direct electrolytic water-splitting process working with thermopiles or photopiles solar plants as electricity source. (23 refs.) | |
| 78107 A solar-hydrogen economy for USA. J.O'M.Bockris, T.N.Vezirloglu (Texas A&M Univ., Coll. Station, TX, USA). <i>Int. J. Hydrogen-Energy (GB)</i> , vol.8, no.5, p.323-40 (1983). For the post-fossil fuel era, there are two main options. One is well known: a fusion hydrogen combination, in which fusion is the primary energy source and hydrogen is the energy carrier. The other option, the solar-hydrogen alternative, is less widely discussed, though it is far more likely to succeed in a reasonable time-scale. It is envisaged that the solar energy will be collected in the highly insulated regions, where it will be used to produce hydrogen from water. Hydrogen would then be transported to consumption centres to meet the energy requirements. There are many ways through which hydrogen can be used in homes and buildings, in cars, in airplanes, in industry, in chemistry and metallurgy, in synthetic food production and in military, more efficiently than any other known fuel. Economically it would not be feasible to replace the fossil-based energy structure all at once, but it would be prudent to start phasing in the solar-hydrogen system by limiting the change to new energy conversion plants. Such a change would be most cost-effective and could be completed in ca 40-60 years—the average life span for energy conversion and distribution systems. To achieve this conversion, a National Energy Resources Executive is recommended. (55 refs.) | |

| 78108 An evaluation of soil sampling for ¹³⁷ Cs using various field-sampling volumes. J.W.Nyhan, G.C.White, T.G.Schofield, G.Trujillo (Los Alamos Nat. Lab., Los Alamos, NM, USA). <i>Health Phys. (GB)</i> , vol.44, no.5, p.541-52 (May 1983). The sediments from a liquid effluent receiving area at the Los Alamos National Laboratory and soils from an intensive study area in the fallout pathway of Trinity were sampled for ¹³⁷ Cs using 25-, 500-, 2500- and 12500-cm ³ field sampling volumes. A highly replicated sampling program was used to determine mean concentrations and inventories of ¹³⁷ Cs at each site, as well as estimates of spatial, aliquoting, and counting variance components of the radionuclide data. The sampling methods were also analyzed as a function of soil size fractions collected in each field sampling volume and of the total cost of the program for a given variation in the radionuclide survey results. Coefficients of variation (CV) of ¹³⁷ Cs inventory estimates ranged from 0.063 to 0.14 for Mortandad Canyon sediments, whereas CV values for Trinity soils were observed from 0.38 to 0.57. 86.70G Atmosphere

78111 Examination of a hot particle from a recent atmospheric test. I.Maschek, T.Csepregi ('Frederic Joliot-Curie' Nat. Res. Inst. for Radiobiology & Radiohygiene, Budapest, Hungary). *Acta Phys. Acad. Sci. Hung. (Hungary)*, vol.52, no.3-4, p.405-11 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981). Changes in airborne activity concentration can usually be observed by determining the radioactivity of collected aerosol. A hot particle was found on an aerosol sample. The hot particle contained fission nuclides like ^{95}Zr and ^{95}Nb , it was solely present on the sample, it originated in the atmospheric nuclear test of 16 October 1980, it was captured a few days before reaching the maximum activity of ^{95}Nb induced directly by ^{95}Zr , and finally its size was about one micrometer. (4 refs.)

78112 Parametrization of air pollution in the surface layer of a complex of transforming and interacting admixtures. K.G.Ganev, D.L.Yordanov (Geophys. Inst., Bulgarian Acad. of Sci., Sofia, Bulgaria). *C.R. Acad. Bulg. Sci. (Bulgaria)*, vol.36, no.1, p.69-72 (1983). A method for the parametrization of pollution is generalized in the case of surface layer pollution by a number of different weightless admixtures which interact and turn into one another. The approximation of stationary turbulent diffusion of admixtures from an infinite flat horizontal homogeneous source in a stationary and horizontal homogeneous surface layer is included. (2 refs.)

78113 An exact solution to the Gaussian cloud approximation for γ absorbed dose due to a ground-level release. T.J.Overcamp, R.A.Feld (Environmental Systems Engng., Clemson Univ., Clemson, SC, USA). *Health Phys. (GB)*, vol.44, no.4, p.367-72 (April 1983). An exact solution is presented for the classical Gaussian cloud approximation for long-term averaged estimates of γ adsorbed dose due to a ground-level release of radioactive gases and particles. The solution is in the form of relatively simple functions and is much easier to implement than the traditional solution. Also, it is shown that the Gaussian cloud approximation predicts lower absorbed dose than the uniform cloud approximation. The difference is significant when the product of γ attenuation coefficient and vertical dispersion coefficient is small. Since the Gaussian cloud approximation is based on a more realistic concentration distribution than the uniform cloud approximation, the calculations using the former should give more accurate estimates of the long-term averaged dose for the sector-averaged plume. (6 refs.)

78114 Uncertainties of predictions of future atmospheric CO_2 concentrations. H.Oeschger, M.Heimann (Phys. Inst., Univ. of Bern, Bern, Switzerland). *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1258-62 (20 Feb. 1983). (Symposium on the Rise in Atmospheric Carbon Dioxide, Bern, Switzerland, 14-18 Sept. 1981). Linear carbon cycle models, tuned to reproduce the CO_2 increase observed at Mauna Loa, independently of their individual assumptions, predict almost identical CO_2 concentration trends for fossil energy scenarios assuming a slightly increasing production in the next few decades. The basic information for such prognoses therefore is the airborne fraction observed over the last 20 years. Uncertainties in this quantity are due to possible errors in the estimate of fossil fuel consumption and the corresponding CO_2 emission, possible natural fluctuations in the baseline CO_2 level, and uncertainties regarding the biospheric CO_2 input and uptake as a result of deforestation and reforestation and land management. Depending on different assumptions the effective airborne fraction, defined as the ratio of CO_2 increase due to fossil fuel CO_2 alone to the integrated CO_2 production, might be as low as 0.38 or as high as 0.72, compared to the apparent airborne fraction of 0.55. (16 refs.)

78115 Distribution of and changes in industrial carbon dioxide production. R.M.Rotty (Inst. for Energy Analysis, Oak Ridge Assoc. Univ., Oak Ridge, TN, USA). *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1301-8 (20 Feb. 1983). (Symposium on the Rise in Atmospheric Carbon Dioxide, Bern, Switzerland, 14-18 Sept. 1981). The burning of fossil fuels is believed to be the major source responsible for an observed increase in the concentration of carbon dioxide in the atmosphere. This paper revises earlier published data on the annual amounts of carbon released to the atmosphere during the period 1950-1978 and updates the record through 1980. A latitudinal distribution of the fossil fuel source is presented as an aid in explaining the differences in the observed CO_2 concentrations at several stations. The latitudinal distribution of the fossil fuel production of CO_2 should be an important aid in carbon-cycle analysis. (17 refs.)

78116 Detection and identification of emission sources on the basis of the trace element composition of aerosols. J.Berzi, G.Koomley, Zs.Molnar, T.Varkonyi (Nuclear Training Reactor, Tech. Univ. of Budapest, Budapest, Hungary). *Period. Polytech. Electr. Eng. (Hungary)*, vol.26, no.1-2, p.123-37 (1982). In the course of these investigations, a method to accurately determine the main and trace elements of aerosols in the atmosphere has been developed. In the basis of the results of chemical analysis, two methods, different in principle, to identify the emission sources are discussed. These methods were used to prove the doubtless relation between environmental samples and samples obtained from the flue of the power plant in different points and at different times on the basis of an analysis of emission and environmental samples resulting from the Komlo Power Plant and its environment. The analytical and computation method developed is considered to be suited for handling more complex environmental problems where more emission sources have to be identified, and their contribution to the combination of the environment has to be determined exactly. 78117 Physical parameters at the valuation of the annoyance of industrial noises. W.Brennecke, H.Remmers (Fachbereich Phys., Univ. Oldenburg, Oldenburg, Germany). *Acustica (Germany)*, vol.52, no.5, p.279-89 (April 1983). In German. 25 representative industrial noises are presented to 80 subjects for the evaluation of annoyance by pair-comparison. The evaluation of the subjective estimation is made by the process of the principle components analysis. Relevant acoustic parameters, whose measuring methods are presented and discussed, are taken for correlation with these results. In addition to the loudness it is especially the sharpness of the noises which delivers significant correlations with the subjectively perceived annoyance. After equalization of the sound level of the noises to a medium level-value, it is also the roughness and tonality which show significant correlations with the factors from the preference analysis. (28 refs.)

86.70L Measurement techniques in environmental science

78118 Repetitive scanning type self-modulation spectroscopy applied to a monitor of ambient air pollution. T.Izumi, N.Takeda. *Anritsu Tech. Bull. (Japan)*, no.44, p.57-67 (March 1983). In Japanese. Design principles of the self-modulation spectroscopy (SELMOD) are discussed and in particular an improved SELMOD system to which a wavelength scanning and a moving average technique are introduced. In this improved method, the average of the second derivative spectra is obtained by repetitive wavelength scanning, and both the sensitivity and stability are remarkably improved. Experimental results show the lower detection limit of the instantaneous reading of the concentration for NO_2 and both SO_2 and NO is 2-3 ppb and 5-6 ppb respectively, even if the ambient temperature fluctuates between 0-40°C. (8 refs.)

78119 SO_2 -measurement with the new UV-BINOS. G.Wiegleb, A.Radow, R.Ross (Leybold Heraeus GmbH, Hanau, Germany). *Tech. Mess. tm (Germany)*, vol.50, no.4, p.143-50 (April 1983). In German. Sulphur dioxide (SO_2) is one of the most important industrial gases. The present SO_2 -measuring technique in process control and exhaust-monitoring is based on the IR-absorption principle. This principle has some disadvantages such as water vapour interference and resolution limitation. An absorption measurement in the UV-range around 285 nm with the BINOS-system doesn't have these disadvantages, so that it is possible to measure SO_2 -concentrations up to 100 ppm and a resolution of 0.1 ppm without water vapour interference. 87.15 MOLECULAR BIOPHYSICS

(see also 36.20 Macromolecules and polymer molecules)

- 78120** Intermolecular interactions for phosphatidyl choline and phosphatidyl ethanolamine. R.Flaim, S.E.Friberg (Chem. Dept., Univ. of Missouri-Rolla, Rolla, MI, USA), P.L.M.Plummer. *Colloids & Surf. (Netherlands)*, vol.6, no.4, p.395-404 (May 1983). Intermolecular interaction between pairs of methylphosphocholine (MPC) and methylphosphoethanolamine were calculated using an extended CNDO/2 program. Experimentally determined conformations were used for the ethanolamine and chlorine groups. In the methylphosphocholine the major interaction was intramolecular, involving the phosphate ester-choline groups, while in the ethanolamine the maximum attraction was intermolecular between the ethanolamine and the phosphate ester of a neighboring molecule(s). (21 refs.)
- 78121** Comparison of theoretical and thermodynamic values of interconstituent interactions in DNA. M.Shibata, T.Kieber-Emmons, R.Rein (Dept. of Experimental Pathology & Biophys., Roswell Park Memorial Inst., Buffalo, NY, USA). *Int. J. Quantum Chem. (USA)*, vol.23, no.4, p.1283-93 (April 1983). Experimental base stacking and hydrogen bonding enthalpies, as determined from double standard DNA melting studies, are compared with theoretical calculations of interactions between the respective DNA interconstituent components. Comparisons are made in relation to the differences in magnitudes, sequence dependent spreads, and trends. It is shown that the use of an effective dielectric constant reconciles the differences between the experimental and theoretical values. Suggestions are made for calibration of potential functions suitable for nucleic acid conformational analysis. (31 refs.)
- 78122** β -lactam ring stability and antibacterial potency: a novel eigenvalue problem. R.H.Davies, T.R.Morris (ICI plc, Macclesfield, England). *Int. J. Quantum Chem. (USA)*, vol.23, no.4, p.1385-405 (April 1983). Low inoculum potency data in vitro for 16 clinical β -lactam antibiotics have been analyzed, and a physical model for interpreting the results of a number of bacterial strains has been derived. An analytic criterion for performing a unitary transformation on the potency data is developed following the identification of a physical vector present within the data which is attributable to an activation energy required for the transport of the β -lactam into a biological membrane. This vector has inverse slope relations in Gram positive and Gram negative bacteria and provides the basis for the analytic criterion for the unitary transformation. Compounds with similar potency spectra which differ only in the absolute magnitude of their effect will possess similar transport properties. It is shown that a slow rate of membrane entry for the β -lactam has overriding consequences on differences in fast rates of binding to the target enzymes and to β -lactamases, and a second primary vector is established directly from the biological data related to the case of β -lactam ring opening. This vector offers precise evidence for testing the solvational and theoretical requirements for predicting the biological stability of novel β -lactam ring compounds. (21 refs.)
- 78123** Evidence for coherent excitation in biological systems. H.Frohlich (Dept. of Phys., Univ. of Liverpool, Liverpool, England). *Int. J. Quantum Chem. (USA)*, vol.23, no.4, p.1589-95 (April 1983). From theoretical considerations, three types of coherent excitations of biological systems have been suggested: (i) vibrations of membranes and of proteins with frequencies above 10^9 Hz; (ii) near static excitation of a highly polar metastable state; and (iii) low frequency periodic enzyme reactions. Recent experimental evidence is discussed. (32 refs.)
- 78124** Energy transfer in B-DNA: mechanism and effects. P.Beaconsfield, E.Balanovski (Bedford Coll. Univ. of London, London, England). *Phys. Lett. A (Netherlands)*, vol.95A, no.8, p.454-6 (23 May 1983). Calculations are presented of effective soliton mass, coupling constant between intermolecular excitation and chain displacement, and energy transfer in B-DNA. (7 refs.)

87.15B Structure, configuration, conformation, and active sites at the biomolecular level

- 78125** The structure of ribosomal proteins. I.N.Serdyuk (Inst. of Protein Res., Acad. of Sci., Poustchino, USSR). *Comments Mol. & Cell. Biophys. Comments Mod. Biol. Part A (GB)*, vol.2, no.1, p.17-39 (April 1983). This review is to give a description of the results of physical experiments undertaken at the author's institute on the small subparticle of *E. coli* ribosomes. As a result of these experiments it is concluded that the greatest part of ribosomal proteins can be described as globular compact molecules both in solution and within the ribosome. (45 refs.)
- 78126** The structure of bovine rhodopsin. P.A.Hargrave (Dept. of Medical Biochem., School of Medicine, Southern Illinois Univ., Carbondale, IL, USA), J.H.McDowell, D.R.Curtis, J.K.Wang, E.Juszczak, Shao-Ling Fong, J.K.Mohana Rao, P.Argos. *Biophys. Struct. & Mech. (Germany)*, vol.9, no.4, p.235-44 (1983). The authors have isolated 16 peptides from a cyanogen bromide digest of rhodopsin. These cyanogen bromide peptides account for the complete composition of the protein. Methionine-containing peptides from other chemical and enzymatic digests of rhodopsin have allowed the authors to place the

cyanogen bromide peptides in order, yielding the sequence of the protein. They have completed the sequence of most of the cyanogen bromide peptides. This information, in conjunction with that from other laboratories, forms the basis for their prediction of the secondary structure of the protein and how it may be arranged in the disk membrane. (17 refs.)

78127 The structure of Panulirus interruptus hemocyanin at 4.0 Å resolution and a preliminary description of the copper-containing oxygen binding site. W.P.J.Gaykema, E.J.M.van Schaick, W.G.Schutter, W.G.J.Hol (Dept. of Chem., Univ. of Groningen, Groningen, Netherlands). *Chem. Scr. (Sweden)*, vol.21, no.1-5, p.19-23 (1983). The hemocyanin from the spiny lobster *Panulirus interruptus*, a hexamer with a molecular weight of approximately 540000, was crystallized with the complete molecule in the asymmetric unit. X-ray diffraction data to 4 Å resolution were collected by the oscillation method for the native crystals and two isomorphous derivatives. The K_2PtCl_4 derivative contained 36 heavy atom sites and the *o*-mercury phenol derivative 70 sites. From the heavy atom positions the 32 point group symmetry of the hemocyanin molecule could be deduced, and the molecular centre accurately established. Multiple isomorphous phases were used for the calculation of an electron density distribution from which the molecular envelope could be obtained. A few cycles of density averaging and phase improvement procedures yielded a much better quality map. Due to the low pH of the crystallization medium, the structure observed is presumably deoxy hemocyanin. (32 refs.)

78128 Three-dimensional structure of membrane-bound cytochrome c oxidase. J.F.Deatherage, R.Henderson, R.A.Capaldi (MRC Lab. of Molecular Biology, Cambridge, England). *Chem. Scr. (Sweden)*, vol.21, no.1-5, p.35-9 (1983). The authors have determined the three-dimensional structure of cytochrome c oxidase in the membrane to a resolution of 20 Å by electron microscopy of two-dimensional vesicle crystals. They investigated the three-dimensional structure of the enzyme by analysis of electron micrographs of tilted, negatively-stained specimens. The resulting map showed the shape of the part of the cytochrome c oxidase molecule which protrudes from the lipid bilayer. The projected structure of the parts of the molecule which are buried in the phospholipid bilayer was determined by electron microscopy of glucose-embedded vesicle crystals. The authors then determined the relative locations of the protruding (solvent-exposed) and buried (membrane-bound) domains of the molecule by varying the density of the embedding medium in electron microscopy. By combining information from these studies, they derived the full connected three-dimensional structure and its relationship to the bilayer. (15 refs.)

78129 The metal centers of cytochrome c oxidase: structures and interactions. D.F.Blair, C.T.Martin, J.Gelles, Hsin Wang, G.W.Brudvig, T.H.Stevens, S.I.Chan (A.Noyes Lab. of Chem. Phys., California Inst. of Technol., Pasadena, CA, USA). *Chem. Scr. (Sweden)*, vol.21, no.1-5, p.43-53 (1983). Studies directed toward the elucidation of the structures of the metal centers in cytochrome c oxidase are reviewed. Progress towards an understanding of the interactions between these centers and their spatial distributions within the protein is also presented. The authors' studies are based primarily on optical and low-temperature electron paramagnetic resonance (EPR) spectroscopy. They have employed nitric oxide (NO), as well as other exogenous ligands, to probe the O_2 reduction site of the enzyme. In addition, they have isolated auxotrophs of *Saccharomyces cerevisiae* in order to metabolically incorporate isotopically substituted amino acids into the yeast protein. Low-temperature EPR and electron nuclear double resonance (ENDOR) spectroscopic studies of these isotopically substituted derivatives have provided unambiguous information on the structure of two of the four metal centers. The degree to which metal centers within the protein interact with one another has been assessed by examining the extent to which redox changes of one metal center modulate changes in the EPR and optical characteristics of the other centers. Conceptions about the overall spatial distribution of the metal centers within the protein emerge from these data. The implications of the authors' results with respect to the mechanisms of dioxygen reduction and energy conservation in cytochrome c oxidase are discussed. (54 refs.)

78130 Structural studies of a bacteriochlorophyll-containing protein. M.F.Schmid, D.E.Tröndrud, B.W.Matthews (Dept. of Phys., Univ. of Oregon, Eugene, OR, USA). *Chem. Scr. (Sweden)*, vol.21, no.1-5, p.67-9 (1983). The bacteriochlorophyll *a*-protein from the green photosynthetic bacterium *Prosthechloris aestuarii* consists of three identical subunits, each of which has a core of seven bacteriochlorophyll *a* molecules enclosed within a 'bag' of protein. The bacteriochlorophylls are arranged in an irregular manner, suggesting that this may be the case in other bacteriochlorophyll-protein complexes. The arrangement of the phytol chains may serve as a model for lipid-protein interactions. In the bacteriochlorophyll protein, the phytol tails have irregular conformations but are not disordered, the bends occur at substituted positions, and the chains have predominantly parallel interactions. Each of the seven magnesiums appear to be five-coordinate; in five cases the presumed ligand is a histidine side-chain, in one case a polypeptide carbonyl oxygen and in the other case a water molecule. Diffraction data to a resolution of 1.9 Å have been collected by oscillation photography, and the refinement of the structure is nearing completion (crystallographic residual $R=20.4\%$). (12 refs.)

78131 Theoretical studies of the electrostatic stability of A, B, C, and Z-DNA conformers as a function of monovalent ion concentration and ion type. B.J.Klein, G.R.Pack (Dept. of Biomedical Sci., Univ. of Illinois Coll. of Medicine, Rockford, IL, USA). *J. Biol. Phys. (USA)*, vol.11, no.1, p.23-5 (1983). Theoretical calculations using a two-state model of counterion-phosphate interactions have been performed in order to determine the electrostatic stability of DNA in various ionic environments. Comparison of the stabilities of different conformations leads to results consistent with the B \rightarrow Z transitions observed in high-salt environments and suggest that a very low ionic strengths the left-handed Z(II) form is an electrostatically preferred conformation. An ion-type dependence of the high-salt B \rightarrow Z transition midpoint is predicted. Calculations of the energies of the A and C conformations are also discussed in relation to experimentally observed transitions. (28 refs.)

78132 Possible incorporation of the purine-purine mispairs in the DNA helix and the interpretation of the transversion-type point mutations. V.Kothekar, G.Bolis, R.Rein (Dept. of Experimental Pathology, Roswell Park Memorial Inst., Buffalo, NY, USA). *Int. J. Quantum Chem. (USA)*, vol.23, no.4, p.1295-303 (April 1983). The stereochemical and energetic compatibility of incorporation of the non-Watson-Crick hydrogen bonded purine-purine base pairs of normal tautomers in the helical structure of B-DNA is studied. The hydrogen bonding positions of the possible 'mispairs' of the bases GA, GG, and AA are optimized first in the base plane by translational and rotational movement along the hydrogen bonds and then introduced at an appropriate position in the

DNA structure. The optimum backbone geometries which can accommodate the 'mispairs' are obtained by force field computations. The stereochemical and energetic aspects of the various mispairs are discussed in light of their possible incorporation in DNA and as mutational intermediates for the 'transversion'-type point mutations. (32 refs.)

78133 Theory of living state. VII. Bose-Einstein-like ordering in temperature and time domain. R.K.Mishra, K.Bhowmik (Dept. of Biophys., All-India Inst. of Medical Sci., New Delhi, India). *Int. J. Quantum Chem. (USA)*, vol.23, no.4, p.1579-87 (April 1983). The Bose-Einstein-like ordering was earlier proposed as an important mechanism of energy handling in the living systems. In this regard two questions arise at once: (1) is such ordering feasible at body temperature and (2) what is the time that may be taken for establishing coherence? The authors answer and satisfy these two questions. (9 refs.)

78134 Structure-activity relationship and the mechanism of analgesia of the analgesic drug 3-methyl-fentanyl and its analogs. Chen Changying, Li Leming (Dept. of Chem., Peking Univ., Beijing, China). *Int. J. Quantum Chem. (USA)*, vol.23, no.4, p.1597-608 (April 1983). The semiempirical self-consistent field MO (CNDO/2) calculations have been undertaken for 13 compounds involving 3-methyl-fentanyl and its analogs. Various quantum chemical indices were obtained. The relationships between the biological activity and quantum chemical indices of molecules of these compounds were investigated and it was found that there are remarkable relationships between the activity and some important quantum chemical indices such as the π -electron density of β substituent and the electron density of piperidyl nitrogen. The nature of interaction between the analgesics' molecule and the receptor was discussed on the basis of the relationships between the activity and quantum chemical indices and it was proposed that the β -substituent functions not only as a hydrophobic group, but also its electronic property has important effect on the activity. It may act as an electron acceptor and form acceptor-donor complex with receptor through the charge transfer process. The piperidyl nitrogen interacts with receptor forming quaternary ammonium ion and acting as positive charge center, and its electron density also has an important effect on the activity. The amide oxygen and nitrogen may be other active centers which function as donors when they interact with the receptor. The influence on activity through introduction of the hydroxyl group to the β -position of the 1-substituent of the piperidyl ring has also been discussed. (32 refs.)

78135 Quantum chemical study of the molecular patterns of MAO inhibitors and substrates. M.Martin, F.Sanz, M.Campillo, L.Pardo, J.Perez, J.Turmo (Dept. of Bioestadística, Univ. Autònoma de Barcelona, Barcelona, Spain). *Int. J. Quantum Chem. (USA)*, vol.23, no.4, p.1627-41 (April 1983). Similarities and differences between mitochondrial monoamine oxidase (MAO) substrates and inhibitors (both A and B types) are considered, studying quantitatively two molecular electrostatic potential (MEP). The following molecules are considered: substrates: PHEA, BZA, tele-N-methyl-histamine, phenylethanolamine, phenylpropylamine, tryptamine, dopamine, phenoxylethylamine, noradrenaline, serotonin, and *p*-nitro-phenylethanolamine; inhibitors: Deprenil, Clorgyline, and Lilly 51641 (only the moiety involved in the A-B differentiation is considered). The wave functions needed to calculate the analyzed properties are of ab initio quality, and have been calculated in analogous conformations, all near the energetic minima. Electron densities distributions are qualitatively compared by means of a correlation coefficient defined over the whole space. Otherwise, patterns of the possible zones of electrostatic interactions are described by means of the distances and angles between minima, in order to differentiate MAO-A and MAO-B substrates. The results reproduce efficiently the experimental classification and enable one to predict the type of enzymatic action of molecules not yet experimentally classified. (14 refs.)

78136 Small-angle X-ray scattering of chain molecules in a hydrodynamic field. The internal rigidity of double-stranded DNA. B.Sjöberg, R.Österberg (Dept. of Medical Biochem., Univ. of Göteborg, Göteborg, Sweden). *J. Appl. Crystallogr. (Denmark)*, vol.16, pt.3, p.349-53 (1 June 1983). Small-angle X-ray scattering data from flowing solutions of double-stranded calf thymus DNA, in phosphate buffer of pH 6.91 and 0.2 mol dm^{-3} ionic strength, have been recorded over a velocity-gradient range from zero up to a maximum value of 15300 s^{-1} . In comparison with small-angle X-ray measurements performed on stationary solutions, the method of flowing the solution through a capillary tube provides information regarding the internal flexibility of the macromolecule in solution. All the X-ray data recorded in this work can be explained by a slightly modified bead-spring chain model of DNA, which consists of linear segments filled with touching beads. The segments are joined together at the ends to form a long array with complete flexibility at each joint. The lengths of the segments follow a Gaussian distribution with a root-mean-square length equal to 100 nm. The diameter of each bead is equal to 3.0 nm. (22 refs.)

78137 Markov analysis of alpha-helical, beta-sheet and random coil regions of proteins. M.Macchiato (Istituto di Fisica Sperimentale, Napoli, Italy), A.Tramontano. *Lett. Nuovo Cimento (Italy)*, vol.37, ser.2, no.3, p.89-94 (21 May 1983). The rules up to now used to predict the spatial configuration of proteins from their primary structure are mostly based on the recurrence analysis of some doublets, triplets and so on of contiguous amino acids, but they do not take into account the correlation characteristics of the whole amino acid sequence. The authors have carried out a statistical analysis of amino acid sequences for the alpha-helical, beta-sheet and random coil regions of about twenty proteins with known secondary structure by considering correlation effects. The results demonstrate that these sequences are at least a second-order Markov chain i.e. they appear as if they were generated by a source that remembers at least the two aminoacids before the one being generated and that these two previous symbols influence the present choice. (10 refs.)

78138 Polyoma virus 'hexamer' tubes consist of paired pentamers. T.S.Baker, D.L.D.Caspar (Rosentel Basic Medical Sci. Res. Center, Brandeis Univ., Waltham, MA, USA), W.T.Murakami. *Nature (GB)*, vol.303, no.5916, p.446-8 (2 June 1983). The authors examination of negatively-stained polyoma virus tubes by digital image processing of low-irradiation electron micrographs shows that all tubes are assemblies of paired pentameric capsomeres. They report that the packing arrangement of the pentamers in the hexamer tubes is simply related to the pentagonal tessellation representing the packing in the narrow pentamer tubes. In all the tube structures examined, at least one pairwise contact between neighbouring pentamers closely resembles the contact between the pentavalent and hexavalent capsomeres in the icosahedral capsid. (8 refs.)

87.15M Interactions with radiations at the biomolecular level

78139 Fluorescence of blowfly metarhodopsin. D.G.Stavenga (Dept. of Biophys., Rijksuniv. Groningen, Groningen, Netherlands). *Biophys. Struct. & Mech. (Germany)*, vol.9, no.4, p.309-17 (1983). The visual pigment of blowfly peripheral photoreceptors displays a marked red fluorescence when the pigment is in the metarhodopsin state as demonstrated in vivo by simultaneous measurements of transmission and fluorescence. The rhodopsin state is non-fluorescent. It is argued that fluorescence offers a unique means to study visual pigment properties in completely intact living animals and, furthermore, provides the opportunity for studying the photoreceptor optics of visual waveguides. As an example the action of the pupil mechanism of blowfly visual sense cells on the fluorescence signal is demonstrated. (28 refs.)

78140 Thermally stimulated luminescence studies of X-irradiated L-alanine:Cr³⁺ single crystals. D.W.Cooke, M.S.Jahan (Dept. of Phys., Memphis State Univ., Memphis, TN, USA). *J. Chem. Phys. (USA)*, vol.78, no.11, p.6477-83 (1 June 1983). Thermally stimulated luminescence studies of X-irradiated L-alanine:Cr³⁺ have been conducted in the interval 10-300K. Glow peaks were observed at 42, 60, 72, 148, and 208K. The 148K peak has been previously reported, while the one at 208K was of insufficient intensity to study. Also, the 60K peak was difficult to analyze due to overlap with the neighboring peaks. Detailed analyses of the 42 and 72K peaks yielded, respectively, the following parameters: $E=24 \text{ meV}$, $s=5.3 \text{ s}^{-1}$, and $l=1$; $E=180 \text{ meV}$, $s=2.4 \times 10^{10} \text{ s}^{-1}$, and $l=2.8$, where l is the kinetics order. Identical emission was observed from each peak, characterized by a maximum at 445 nm with FWHM equal to 0.605 eV. A tentative model is presented to explain these results in terms of detrapping and deexcitation via the excited singlet and triplet states. (43 refs.)

78141 Long-wavelength-absorbing forms of bacteriochlorophyll *a* in solutions of Triton X-100. J.Gottstein, H.Scheer (Botanisches Inst., Univ. München, München, Germany). *Proc. Natl. Acad. Sci. USA*, vol.80, no.8, p.2231-4 (April 1983). At least three forms of Triton X-100-solubilized bacteriochlorophyll *a* (Bchl *a*) have been characterized by UV/visible/near-IR absorption and CD spectra. One, absorbing at 770 nm, is similar to a monomeric solution in methanol. The two others have strongly red-shifted absorption peaks (860 nm and 930, 835 nm) and intense and complex CD bands in this region, indicative of strong interaction of at least two and three molecules of Bchl *a*, respectively. (53 refs.)

78142 Nanosecond absorption spectroscopy of hemoglobin: elementary processes in kinetic cooperativity. J.Hofrichter, J.H.Sommer, E.R.Henry, W.A.Eaton (Lab. of Chem. Phys., Nat. Inst. of Health, Bethesda, MD, USA).

Proc. Natl. Acad. Sci. USA, vol.80, no.8, p.2235-9 (April 1983). A nanosecond absorption spectrometer has been used to measure the optical spectra of hemoglobin between 3 ns and 100 ms after photolysis of the CO complex. The data from a single experiment comprise a surface, defined by the time-ordered set of 50-100 spectra. Singular value decomposition is used to represent the observed spectra in terms of a minimal set of basis spectra and the time course of their amplitudes. Both CO rebinding and conformational changes are found to be multiphasic. Prior to the quaternary structural change, two relaxations are observed that are assigned to germinate recombination followed by a tertiary structural change. These relaxations are interpreted in terms of a kinetic model that points out their potential role in kinetic cooperativity. The rapid escape of CO from the heme pocket compared with the rate of rebinding observed for both *R* and *T* quaternary states shows that the quaternary structure controls the overall dissociation rate by changing the rate at which the Fe-CO bond is broken. A comparable description of the control of the overall association rates must await a more complete experimental description of the kinetics of the quaternary *T* state. (28 refs.)

87.16 BIOTHERMICS

78143 The thermotropic properties of coenzyme Q₁₀ and its lower homologues. H.Katsikas, P.J.Quinn.

J. Bioenerg. & Biomembranes (USA), vol.15, no.2, p.67-79 (April 1983). The thermotropic properties of coenzymes Q₁₀, Q₉, Q₈, and Q₇ have been examined by differential scanning calorimetry and wide-angle X-ray diffraction. Typical scanning calorimetry cooling curves of coenzyme Q from the liquid state exhibit a single exothermic phase transition into a crystalline state at a temperature that decreases as the length of the polyisoprenoid side-chain substituent decreases. Upon subsequent heating, the molecules undergo a series of thermal events which precede the main crystalline-to-liquid endothermic phase transition. The temperature of these transitions increases with increasing chain length. The crystallization phase transition temperature depends markedly on the rate at which the sample is cooled and increases with decreasing scan rate; the temperature of the melting endotherm is not markedly affected by the scan rate. Detailed calorimetric studies of coenzyme Q₁₀ indicate that two crystalline states are formed, one at relatively high cooling rates to low temperatures and the other when preparation area cooled slowly from the liquid state to relatively high temperatures. Heating the crystalline phase formed by rapid cooling causes its transformation into the phase observed by cooling slowly. X-ray diffraction analysis confirmed the existence of these two crystal phases in coenzymes Q₉ and Q₁₀ and the transformation from the rapidly crystallized form to the more ordered form associated with slower cooling rates. At body temperature (310K) under equilibrium conditions coenzyme Q₁₀ exists in an ordered crystalline phase; the implications of the thermotropic behavior of coenzyme Q₁₀ on mitochondrial function in vitro and in vivo are discussed. (22 refs.)

78144 Giant squids may die when exposed to warm water currents. O.Brix (Zoological Lab., Univ. of Bergen, Bergen, Norway).

Nature (GB), vol.303, no.5916, p.422-3 (2 June 1983). Stranding of giant squids in Newfoundland waters has been correlated with the in flow of warm water, suggesting that increased temperature may be causing their death. Squids have also been carried to the Norwegian coast with the warm North Atlantic current and on 23 August 1982 a live specimen was caught off Røddøy near Bergen, Norway. This catch gave an unprecedented opportunity to study the effects of temperature on the oxygen binding properties of blood from the giant squid. The present finding of an excess of a fourfold decrease in O₂ affinity when temperature is increased from 6.4 to 15°C strongly suggests that giant squids may suffocate from arterial desaturation when increased ambient temperatures are experienced. (11 refs.)

78145 Growth of 'black smoker' bacteria at temperatures of at least 250°C. J.A.Baross (School of Oceanography, Oregon State Univ., Corvallis, OR, USA), J.W.Deming.

Nature (GB), vol.303, no.5916, p.423-6 (2 June 1983). Reports that a bacterial community originally cultured from 206°C water is capable of chemolithotrophic growth in a titanium growth chamber under in situ vent pressure of 265 atm and at temperatures of at least 250°C. (At 265 atm, seawater remains liquid at temperatures of at least 460°C.) Transmission electron microscopy of thin sections of bacteria cultured at 250°C has revealed the presence of at least two morphologically distinct organisms. (24 refs.)

87.20 MEMBRANE BIOPHYSICS

78146 Ion distributions in inhomogeneous regions [biomembranes]. V.S.Vaidyanathan (Dept. of Biophys., Cary Hall School of Medicine, State Univ. of New York, Buffalo, NY, USA).

Colloids & Surf. (Netherlands), vol.6, no.4, p.291-306 (May 1983). Based on the premise that ion-ion interaction energy term contributions to the chemical potential of an ionic species in the inhomogeneous region cannot be neglected, the basic nonlinear differential equations relating the electric potential profile, dielectric profile and concentration profiles are formulated. Analytical expressions for solutions of these differential equations are obtained. It is shown that the magnitudes of the inhomogeneous region and electric potential difference are determined by the system in a self-consistent manner. Certain interesting conclusions, in contradiction with classic Gouy-Chapman theory, are obtained. (15 refs.)

78147 Exchange currents across the electrolyte/membrane interface in frog skin. Ming De Li, J.T.Tarvin, M.Ali, D.Bernard, M.A.Dinno (Dept. of Phys. & Astron., Univ. of Mississippi, University, MS, USA).

Colloids & Surf. (Netherlands), vol.6, no.4, p.307-14 (May 1983). Using bipolar current pulses of 1-100 μ A amplitude and 1-50 s duration, the current-over-potential behavior of the frog skin (*Rana pipiens*) has been determined in a bicarbonate-containing Ringer's solution. This behavior is analyzed using a model based on rate theory. In this manner, it is possible to measure both the open-circuit exchange current and the contribution of the membrane potential to the energy barrier representing ionic movement across the frog skin. In a double-exponential least-squares fit of the data, the exchange current was found to be independent of pulse duration, suggesting that the system is already in a steady state by 1s. The experimentally measured current-over-potential curves were asymmetric for hyperpolarization vs. depolarization. This asymmetry is predicted by the authors' model, and suggests that Na⁺ and Cl⁻ do not contribute equally to the exchange current. (9 refs.)

78148 Mass action kinetics of vesicle aggregation and fusion. J.Bentz (Dept. of Pharmacy & Pharmaceutical Chem., Univ. of California, San Francisco, CA, USA), S.Nir, J.Wilschut.

Colloids & Surf. (Netherlands), vol.6, no.4, p.333-63 (May 1983). The kinetics of Ca²⁺-induced fusion of both large and small phosphatidylserine vesicles has been examined theoretically and experimentally. With the

Tb/DPA assay for mixing of vesicle contents, the kinetics of vesicle aggregation can be separated from the kinetics of vesicle fusion by varying the initial concentration of vesicles. Both the rate constant for vesicle dimerization and the rate constant for the actual membrane fusion can be determined by this analysis. The kinetics of release of vesicle contents during and following the fusion event have also been examined. The theoretical analysis can be easily adapted to other fusion assays and, as such, provides a unique opportunity for a quantitative evaluation of the factors which affect the fusion of vesicles such as temperature, cations bound to the lipids, and the membrane composition. The effect of aggregation reversibility on the kinetics of the overall fusion process is considered in detail. Analysis of the initial kinetics of the Ca²⁺-induced fusion of phosphatidylserine vesicles shows that the fusion step itself can be very rapid (of the order of ms-s) and the initial leakage associated with the fusion event, per se, is essentially zero for the large vesicles and quite small for the small vesicles.

78149 Permeability characteristics of the basement membrane (basal lamella) of the intestine of *Ascaris* suum. M.J.Donahue, C.G.Beames, Jr., K.S.Bost (Dept. of Physiological Sci., Oklahoma State Univ., Stillwater, OK, USA).

J. Biol. Phys. (USA), vol.11, no.1, p.11-13 (1983). Permeability characteristics have been determined for isolated ribbons of the basement membrane of the intestine of *Ascaris suum*. The solute permeability coefficient (P_s) was measured for a series of hydrophobic, nonionic molecules of graded molecular size. The geometric pore area per unit path length (A_g/Δx) was estimated to be 24.0 cm from the diffusion rates for the various solute molecules. A filtration coefficient (L_p) of 18.1 × 10⁻¹² cm³/dyne-sec was determined by a method that employs osmotic pressure. The preceding values were used to calculate an average pore radius of 24.0 Å for the membrane. The unstirred layer was estimated to be 30 μ m thick from measurements of the change in the rate of diffusion of water across the membrane with change in the rate of perfusion. The preceding values were used to calculate a reflection coefficient (σ), effective permeability coefficient (ω), and a permeability coefficient (ω). The results support the view that this basement membrane functions as a filter and selective barrier to diffusion of constituents of the worm's body fluid. (19 refs.)

78150 Further comments on negative solvent pressure in osmosis. H.R.Hirsch (Dept. of Physiology & Biophys., Univ. of Kentucky, Lexington, KY, USA).

J. Biol. Phys. (USA), vol.11, no.1, p.26 (1983).

A previously proposed gedanken experiment (see H.R. Hirsch, *ibid.*, vol.8, p.11, 1980) on osmotic pressure and low flow is supplemented to illustrate the circumstances in which equilibrium is achieved. The concept that solvent pressure can be negative and can be described as a partial pressure is thus given additional credence. (2 refs.)

78151 Dual-mode potential oscillations on an immobilized acetylcholinesterase membrane system. T.R.Chay (Dept. of Biological Sci., Univ. of Pittsburgh, Pittsburgh, PA, USA), N.J.Zabusky.

J. Biol. Phys. (USA), vol.11, no.1, p.27-31 (1983).

The authors have studied by numerical simulations the effects of varying external salt concentration on a multibarrier kinetic model of a synthetic membrane system bearing AChE and BSA. For certain parameters, they find a 'spiky' high frequency modulation imposed on a 'bursting' low frequency carrier. In the absence of added salt, oscillations with only one mode arise, consistent with the experimental result of Friboulet and Thomas (1982). From this study, the authors suggest how periodic ionic permeability changes of ions may arise in excitable membranes. (11 refs.)

78152 Electrostatics and gating of excitable membranes. I.Lundstrom, C.Nylander (Dept. of Phys. & Measurement Technol., Linköping, Inst. of Technol., Linköping, Sweden).

Int. J. Quantum Chem. (USA), vol.23, no.4, p.1269-82 (April 1983).

Two electrostatic models for ion permeability of membranes are considered. In the first model ions pass hydrated through the membrane and in the second model ions pass unhydrated through a channel lined with polar groups. In both cases it is found that it is not necessary to assume a high macroscopic dielectric constant of the membrane or channel to provide a low enough potential energy of the ion in the membrane. Gating of excitable membranes is considered a special case of electrostatic interaction in membranes. A simple physical model which fits with Hodgkin and Huxley's empirical relation is derived. Finally, the authors have speculated upon other membrane bound biological phenomena were electrostatic effects may be important. (19 refs.)

78153 Molecular dynamics of a bilayer membrane. P.van der Ploeg, H.J.C.Berendsen (Lab. of Phys. Chem., Univ. of Groningen, Groningen, Netherlands).

Mol. Phys. (GB), vol.49, no.1, p.233-48 (May 1983).

A molecular dynamics simulation was carried out for a bilayer of 2 × 64 decane molecules as a model for a biological membrane. Two dimensional periodic conditions were used and head groups were subjected to a simple mean force interaction. Four runs at two different temperatures and head group densities were executed, each over 80 ps. Molecular order parameters were analysed and compared with experiment. A fluctuating tilt of the molecules occurs with respect to the bilayer normal with a spatial correlation of about 1 nm and a temporal correlation of 8 ps. The molecules do not rotate isotropically around their long axes, and a different behaviour of odd and even numbered bonds is apparent. The density profile shows a dip near the middle of the bilayer and the lateral pressure profile shows a negative region near the head groups compensated by a positive region near the tails. Translational diffusion is inhibited by a long negative tail of the velocity autocorrelation functions, but still exceeds experimental values. The results are discussed in terms of implications for membrane structure. Results confirm earlier simulations on a smaller model (J. Chem. Phys., 76, 3271, 1982), except for the cooperativity of molecular tilt. (27 refs.)

78154 Structural and functional evidence for multiple channel complexes in the outer membrane of *Neurospora crassa* mitochondria. C.A.Mannella (Center for Labs. & Res., New York State Dept. of Health, Albany, NY, USA), N.C.Colombini, J.Frank.

Proc. Natl. Acad. Sci. USA, vol.80, no.8, p.2243-7 (April 1983).

The outer membrane of mitochondria contains proteins that form channels called VDAC (voltage-dependent anion-selective channels). Two independent lines of evidence suggest that these channels occur in specific complexes in the outer membrane of *Neurospora crassa* mitochondria. Electron microscopic images of these outer membranes reveal polymorphic crystalline arrays of putative pores. These arrays can be shown to be interrelated by movement in the membrane plane of a particular rigid channel triplet or of regular aggregates of this triplet. Detergent extracts of the same outer membranes induce single- and multiple-step conductances in planar phospholipid membranes, with a marked preference for the insertion of triplets and multiples of triplets. The tendency of the mitochondrial channels, to occur as extended arrays,

apparently built up from triplets, may have important functional and evolutionary implications. (29 refs.)

78155 Aggregation and fusion of phospholipid vesicles. S.Nir (Seagram Centre for Soil & Water Sci., Hebrew Univ. of Jerusalem, Rehovot, Israel), J.Bentz, J.Wilschut, N.Duzgunes. *Prog. Surf. Sci. (GB)*, vol.13, no.1, p.1-124 (1983). Membrane fusion and aggregation of phospholipid vesicles are reviewed and discussed. The fusion process is viewed as consisting of several stages: aggregation and close apposition of the particles, destabilization, and finally, merging of the bilayers. A procedure is presented which yields both the rate constant of the dimerization (C_{11}) and the rate constant for fusion of the dimers (f_{11}), which is a direct measure of the probability that two apposed vesicles will fuse. Experimental methods used in the study of membrane fusion are reviewed, primarily with respect to their capacity to monitor the kinetics of vesicle fusion. A few kinetic studies on the mixing of aqueous contents, leakage and increase in size of fusing vesicles are presented in detail. Factors affecting fusion such as cations, temperature, membrane composition vesicle concentration and size are reviewed and analyzed. Di- or trivalent cations induce fusion of acidic phospholipid vesicles (except for phosphatidylinositol) in either pure or mixed form. Among the neutral phospholipids, phosphatidylcholine (PC) inhibits but phosphatidylethanolamine (PE) sustains or enhances the fusion capacity of acidic phospholipid vesicles. Monovalent cations induce reversible aggregation of negatively charged vesicles, but they inhibit the fusion induced by divalent cations such as Ca^{2+} or Mg^{2+} . (303 refs.)

87.25 CELLULAR BIOPHYSICS

78156 Contractils: quantum mechanical fibrils. S.Rowlands, C.P.Eisenberg, L.S.Sewchand (Faculty of Medicine, Univ. of Calgary, Calgary, Alberta, Canada).

J. Biol. Phys. (USA), vol.11, no.1, p.1-4 (1983). When an erythrocyte rouleau is pulled apart by micromanipulation the cells remain attached to each other by long fibrils which may reach lengths of over 100 μm . The tension and length of the fibrils are drastically reduced when the cellular membrane potential is abolished or when the cells are depleted of ATP. It is inferred that the fibrils consist of macromolecules and that the tension is largely derived from a quantum mechanical long-range interaction which accords with the theory of Frohlich. (20 refs.)

78157 Dielectric measurements on live biological materials under magnetic resonance conditions. A.H.Jafary-Asl, S.N.Solanki, E.Aarholt, C.W.Smith (Dept. of Electronic & Electrical Engng., Univ. of Salford, Salford, England).

J. Biol. Phys. (USA), vol.11, no.1, p.15-22 (1983). In the course of work on the interactions of electric and magnetic fields with both living and dead biological materials, it was noticed that certain published dielectrophoretic yield curves for biological cells showed unexplained deviations in the region of 2 kHz. Dielectrophoretic measurements made at frequencies and magnetic fields which satisfied the nuclear magnetic resonance conditions showed sharply resonant features. Dielectric measurements showed small, but sharp, resonances most easily seen in the dielectric loss curves which had a bandwidth of the order of one Hertz and presented at the frequencies which satisfied the magnetic resonance conditions for the ambient magnetic field. Resonances were found corresponding to the frequencies for electron spin resonance and nuclear magnetic resonance for ^1H , ^{31}P , ^{23}Na , ^{37}Cl and ^{39}K . The onset of these resonances occurs at the value of the steady magnetic field strength so that one quantum of magnetic flux (2.07×10^{-15} wb) would link a single biological cell or pair of cells, approximately 1 G (100 μT) in the case of a 5- μm yeast cell. The effects of these magnetic resonance conditions on the mean generation time of *E. coli* and on the reaction of the enzyme lysozyme with the substrate *m. lysodeikticus* cells are also shown. (9 refs.)

78158 Understanding blood cell motion. M.D.Levine (Dept. of Electrical Engng., McGill Univ., Montreal, Quebec, Canada), P.B.Noble, Y.M.Youssef. *Comput. Vision, Graphics & Image Process. (USA)*, vol.21, no.1, p.58-84 (Jan. 1983).

The main function of the surface of a blood cell is to receive information from the environment. Experiments have indicated that the cell membrane plays a vital role in the life, development, and regulation of cells. There is, however, no existing method to quantify the observable changes in membrane shape that occur in locomotion. This paper describes research to develop an image interpretation system capable of analyzing the structural changes in the morphology of cells from a sequence of pictures, using automatic techniques of image processing. A model for a general dynamic scene analysis system is described. It consists of three basic entities: dynamic data, static data, and a collection of analysis processes. Based on this model, a rule-based image interpretation system for moving cells has been implemented. The system consists of different cooperating computational processes, which interact with two common memories, a short term memory (STM) and a long term memory (LTM). The STM contains a dynamic record of the instantaneous cell motion, shape, and structural changes, as well as the current global description of the cell behavior. The LTM data are static, and are implemented as rules. These describe the general model of the morphology of the cells under analysis, as well as control information pertinent to the computational processes. (17 refs.)

78159 Inhibition of repair of radiation-induced strand breaks by hyperthermia, and its relationship to cell survival after hyperthermia alone. J.B.M.Jorritsma, A.W.T.Konings (Dept. of Radiopathology, Univ. of Groningen, Groningen, Netherlands).

Int. J. Radiat. Biol. (GB), vol.43, no.5, p.505-16 (May 1983). Ehrlich ascites cells growing in vitro have been used to investigate the influence of hyperthermia on the formation and repair of DNA strand breaks after X-irradiation. Different heat pretreatments were given immediately prior to a dose of 6 Gy of X-rays. When a temperature of 42°C was used, up to 4 hours of pretreatment had only a slight inhibitory effect on the repair of DNA strand breaks induced by radiation. At a temperature of 43°C progressively more inhibition was observed with longer treatment times. This was also the case for temperatures of 44°C and 45°C. When the treatment times of 43-45°C were longer, strand breaks in DNA were induced by the hyper-

thermic treatment alone. Under these conditions almost no repair was found of strand breaks induced by a subsequent radiation dose. The data obtained strongly suggest a correlation between the effect of the hyperthermic treatment alone on cell survival and the kinetics of repair of strand breaks in DNA as induced by radiation. (24 refs.)

78160 Effects of hyperthermia on the repair of X-ray-induced DNA double strand breaks in mouse L cells. I.R.Radford (Biological Res. Unit, Cancer Inst., Melbourne, Victoria, Australia).

Int. J. Radiat. Biol. (GB), vol.43, no.5, p.551-7 (May 1983). Presents the following observations: (1) X-ray induced DNA double strand break repair can be markedly inhibited by prior hyperthermic treatment. (2) Hyperthermic treatment can enhance the level of DNA double strand breakage produced by subsequent X-irradiation. (3) DNA double strand breakage is detectable in cells given a lethal hyperthermic treatment, following subsequent incubation at 37°C. (16 refs.)

78161 Pointwise bounds for the solution of a nonlinear problem in cell membrane theory. A.M.Arthurs (Dept. of Maths., Univ. of York, York, England), W.M.Arthurs.

Bull. Math. Biol. (GB), vol.45, no.2, p.155-68 (1983).

Pointwise upper and lower bounds for the solution of a class of nonlinear problems arising in the steady-state finite cable model of cell membranes are presented. Simple analytical bounding curves are obtained for an illustrative example in the theory of nerve membranes. (6 refs.)

78162 Effects of alternating electric fields on material transport in heterogeneous media. M.M.Breuer, H.Van Der Lee (Gillette Res. Inst., Rockville, MD, USA).

Colloids & Surf. (Netherlands), vol.6, no.4, p.315-31 (May 1983).

Whenever alternating electric fields act on systems in which gradients of dielectric constants or conductivities exist, charge accumulations occur. As a consequence of these interactions, provided the conductive mode is ionic, material transport will also ensue. The phenomenon is known as dielectric diffusion. The authors derived phenomenological equations expressing the magnitude of this effect under various conditions. Using these equations, they computed material fluxes for a system consisting of fibers immersed into a liquid containing a diffusing material. The results of these calculations suggested that dielectric diffusion could change the rate of material transport into fibers. Using hair fibers immersed in solutions of dyes and other com-

pounds, the authors measured the magnitude of the effects that alternating electric fields of various frequencies and intensities have on the transport of dissolved materials into the fibers. The results indicated that the magnitude and the direction of the effect depended on both the experimental conditions and the nature of the diffusing material. Both enhancement and retardation of material transport could be observed as a result of superimposed alternating electric fields. (12 refs.)

78163 Erythrocytes sedimentation profiles under gravitational field as determined by He-Ne laser. VI. Effect of various hematocrits. K.P.Joseph, Megha Singh (Biomedical Engng. Div., Indian Inst. of Technol., Madras, India). *J. Math. & Phys. Sci. (India)*, vol.16, no.5, p.489-97 (Oct. 1982). [received: May 1983]

Erythrocytes sedimentation profiles, under a gravitational field, for blood samples of different hematocrit are determined. It is observed that the sedimentation profiles, depending on the hematocrit of the sample, differ significantly. This enables one to find the location of any percentage of cells after any specified interval of time. (8 refs.)

78164 Voltage-gated Ca^{2+} channel in mouse myeloma cells. Y.Fukushima, S.Hagiwara (Dept. of Physiology, Univ. of California, Los Angeles, CA, USA).

Proc. Natl. Acad. Sci. USA, vol.80, no.8, p.2240-2 (April 1983). Electrical properties of the cell membrane were studied in the neoplastic lymphocyte, mouse myeloma cell line S194, by using the whole-cell patch clamp technique. Inward Ca^{2+} currents due to voltage-gated Ca^{2+} channels were found. The current, which decayed exponentially after reaching a peak, was first activated at about -50 mV and attained its maximum peak amplitude at about -20 mV in a 10 mM Ca^{2+} solution. Outward current was negligible for the potential range more negative than $+30$ mV. The channel was permeable to Sr^{2+} and Ba^{2+} in addition to Ca^{2+} . Among these species, Sr^{2+} carried the greatest current. The time constants of the decay of the current depended neither on the species nor on the concentration of charge carrier. The steady-state inactivation was observed at potentials more negative than those at which the inward Ca^{2+} current was activated. Thus, it was concluded that the inactivation of the channel was mainly voltage dependent. For reasons that are not yet understood, the amplitude of the Ca^{2+} current varied greatly among cells. (19 refs.)

78165 Establishment of an oscillatory regime in a dissipative biological system. A.M.Kosevich, I.L.Kruglikov (Inst. for Low Temperature Phys. & Engng., Acad. of Sci., Kharkov, Ukrainian SSR). *Phys. Scr. (Sweden)*, vol.27, no.5, p.380-4 (May 1983).

A distributed cell system which exchanges substance with the surrounding medium is considered. The state of the system is described by the cell size distribution function, $f(R,t)$, and the concentration of the nutrient, c , in the solution, which obey a pair of nonlinear equations. The system is characterized by a definite temporal period, connected with the life cycle of an individual cell, and by the average frequency of cell death. It is shown that at constant feeding of substance to the system a stationary regime will be necessarily established in it due time. As a rule, in the stationary regime the function $f(R,t)$ and the concentration c do not depend on time. However, sometimes in the system an oscillatory regime can appear. The sufficient conditions of appearing of such a regime are obtained, and the corresponding oscillations are described. (11 refs.)

87.30 BIOPHYSICS OF NEUROPHYSIOLOGICAL PROCESSES

(exc. perception processes and speech)

78166 EMG activity of the vastus medialis oblique and the vastus lateralis in their role in patellar alignment. L.Reynolds (Dept. of Phys. Therapy, Kaiser Permanente Medical Center, Hayward, CA, USA), T.A.Levin, J.M.Medeiros, N.S.Adler, A.Hallum.

Am. J. Phys. Med. (USA), vol.62, no.2, p.61-70 (April 1983). Using intramuscular electrodes the integrated electromyographic activity of the vastus medialis oblique and the vastus lateralis was examined in twenty normal females. The activity was recorded during the last thirty degrees of distal segment stabilized knee extension, when patellar subluxation commonly occurs. The electromyographic activity was normalized and expressed as a percentage of a maximal isometric contraction. Both muscles exhibited low levels of activity with no significant differences between the two. This study provides a quantitative method to assess whether muscular imbalance is present in patients with patellar subluxation. (33 refs.)

78167 The study of exercise and the relation to Q-T interval. D.E.Biddlecombe, M.J.English (Graduate Div. of Biomedical Engng., Univ. of Sussex, Brighton, England), R.Vincent, D.J.Woolons. *Automedica (GB)*, vol.4, no.4, p.209-16 (1983).

The experimental results reported show that: (1) Q-T interval response lags behind changes in heart rate. (2) More than one value of Q-T interval is possible at any single heart rate. (3) The plot of Q-T interval against heart rate for increasing rates is different to that for decreasing rates (hysteresis). (4) The general appearance and length of a Q-T trace provides an indication of possible cardiac disease. In addition, this method of presentation of the data may be more readily amenable to interpretation than by present means. (2 refs.)

78168 A transfer function model for AV conduction in the human heart. I.Van Der Tweel, J.N.Herbschleb, F.L.Meijler (Dept. of Cardiology, Univ. Hospital, Utrecht, Netherlands). *Automedica (GB)*, vol.4, no.4, p.251-5 (1983).

An effort to explain the conduction through the AV node during random stimulation by fitting a transfer function model to the S-S and S-R intervals is described. Data from 3 patients are analysed. (3 refs.)

78169 Analysis of limit-cycle conditions in intercoupled relay oscillators with reference to gastrointestinal modelling. D.P.Atherton (School of Engng. & Appl. Sci., Univ. of Sussex, Brighton, England), D.A.Linkens. *Bull. Math. Biol. (GB)*, vol.45, no.2, p.239-57 (1983).

Presents an exact analysis of a mutually coupled relay oscillator based on a method originated by Y.Z. Tsytkin (1955). Limit-cycle frequencies and phases can be determined exactly using this method, unlike other approximate methods based on describing functions and harmonic balance techniques. A

new method of exact determination of limit-cycle stability is also shown to give excellent agreement with simulation studies. Different types of intercoupling are shown to give different stability conditions, and these are discussed in relation to gastrointestinal (GI) smooth muscle modelling. GI tract electrical activity has previously been modelled using bidirectionally coupled nonlinear oscillators, and the results of the present analysis of relay oscillators is compared with other studies using Van der Pol dynamics. (32 refs.)

78170 Kinetic theory of neural systems: analysis of the activity of the two-dimensional model. F.Ventriglia (Istituto di Cibernetica, CNR, Napoli, Italy).

Biol. Cybern. (Germany), vol.46, no.2, p.93-9 (1983).

The behaviour of some two-dimensional neural systems is studied by a numerical solution of the associated kinetic equations. The ability of the model to sustain the propagation of informational waves and rhythmic activities as well as memory effects has been demonstrated. (10 refs.)

78171 Evaluation of neuronal coupling dynamics. J.Schneider, R.Eckhorn, H.Reitbock (Philipps-Univ. Marburg, Marburg, Germany).

Biol. Cybern. (Germany), vol.46, no.2, p.129-34 (1983).

Temporary correlated activity of neuron assemblies is believed to play a substantial role for the brain's pattern recognition ability. To study the underlying principles of such mechanisms, a method is proposed for the characterization of the interneuronal and stimulus-response coupling changes of two periodically driven and simultaneously recorded units. The coupling measure is derived from the cross correlation function by calculating the actual correlation contributions without performing the subsequent time-average (which would give the cross correlation function). Examples are given for simultaneously recorded spike trains from visual cortical units, but the method can be applied equally well to evoked potentials or intracellular recordings. (10 refs.)

78172 Bioelectric considerations in the design of high-voltage power lines.

M.Reichmann, A.A.Marino (Dept. of Orthopaedic Surgery, Louisiana State Univ. Medical Center, Shreveport, LA, USA).

J. Bioelectr. (USA), vol.1, no.3, p.329-38 (1982).

Public-health considerations require that all practical steps be taken to minimize the environmental electric and magnetic fields of high-voltage power lines. These fields are influenced not only by the line's operating voltage, but also by various design features including line configuration, phase-spacing, line height, and cable diameter. The largest effect is associated with line configuration. Beyond about 50 meters, the fields of a horizontal line are less than that of the equivalent vertical line; they become progressively more so with increasing distance. As a consequence, for a line having a given energy-carrying capacity, the horizontal configuration minimizes the ground-level fields at points beyond the right-of-way. None of the other design features considered had a significant effect on the fields. (10 refs.)

78173 Electromyographic study of the bulbo-cavernosus muscle in women according to parity and during labor. V.Gallai, C.Firenze, G.Mazzotta, L.Agostini (Inst. of Clinical Neurology, Univ. of Perugia, Perugia, Italy). *Electromyography & Clin. Neurophysiol. (Belgium)*, vol.23, no.3, p.195-201 (March-April 1983).

The bulbo-cavernosus muscle was electromyographically examined in 30 non-pregnant females; and also in 30 females during the expulsion stage of labor, divided into 3 groups according to parity. In the non-pregnant females the action potentials had a duration of amplitude respectively of 4.6 ± 0.7 msec and $303.3 - 20.4$ μ V for the nulliparae; 4.5 ± 0.9 msec and 299.7 ± 28.4 μ V for the uniparae; 4.4 ± 0.8 msec and 281.4 ± 25.6 μ V for the multiparae. In the females during labor the action potentials had a duration and an amplitude respectively of 5.8 ± 0.6 msec and 430.7 ± 28.6 μ V for the uniparae; 5.7 ± 0.5 msec and 413.5 ± 22.5 μ V for the biparae; and 5.1 ± 0.4 msec and 362.5 ± 17.4 μ V for the multiparae. In addition, the bulbo-cavernosus muscle and the external sphincter of the anus in non-pregnant females were examined simultaneously; as was the bulbo-cavernosus muscle and the uterine muscles of pregnant females during the expulsion stage. The authors conclude that the cloaca derived musculature has a synchronous and simultaneous activity, and that the coordination between the uterine muscle activity and that of the perineal diminishes with repeated pregnancies. (7 refs.)

78174 EMG parameters changes in the effort pattern at various loads in diseased muscle. I.Petrusewicz, J.Kocep (Dept. of Neurology, Medical School, Warsaw, Poland). *Electromyography & Clin. Neurophysiol. (Belgium)*, vol.23, no.3, p.213-28 (March-April 1983).

Mechanical and electrical activity in m. biceps brachii during contractions of 10, 30, 50, 70 and 100% of maximal force of the given subject were examined. The investigations were done in a control group of 11 healthy subjects, in 14 cases of myopathy and 11 cases of neurogenic atrophy. The electrical activity was analyzed using a computerized method developed in the authors' institute. The dynamics of increasing density and amplitude and recruitment of motor units up to maximal effort seems to be different in various pathological states of muscle. The authors have also proved the possibility of evaluating the single potential during submaximal effort. (18 refs.)

- 78175 The spectral analysis of the visual evoked potentials of normal and congenital dull children (Down's disease). Xie Zhongjie (Dept. of Maths., Peking Univ., Peking, China). *Acta Sci. Nat. Univ. Pekin. (China)*, no.6, p.91-6 (1982). In Chinese. The statistical analysis shows that the spectral estimates of dull children (near 3 1/3 Hz and 10 Hz) are obviously different from that of normal children. The Bayesian discriminant function clearly divides the sample pairs of two populations into two regions on the plane. (8 refs.)
- 78176 An analogue model of the luminosity-channel in the vertebrate cone retina. I. Hardware and responses to square wave voltages. R.Siminoff (Inst. fur Physiologie, Freien Univ. Berlin, Berlin, Germany). *Biol. Cybern. (Germany)*, vol.46, no.2, p.101-10 (1983). Deals with a description of the hardware for an analogue simulation of the generalized vertebrate cone retina using Eckmiller's (1971) model as a starting point, but modified to be compatible with the author's model. A number of simplifications were made, such as limiting the cone mosaic to only one spectral type of cone, limiting the unit hexagon to only 7 cones and omitting stray light effects and electrical coupling between like-cones. Nevertheless, the model is a realistic representation for a number of simple parameters of the luminosity-channel of the vertebrate cone retina. The feasibility of the model was established by a study of response characteristics to stationary stimuli and noting physiological correlates. The roles of negative feedback from the horizontal cell (HC) to the cones, electrical coupling of HCs and center-surround interactions were elucidated and shown to be important for the organization of the retina. (32 refs.)
- 78177 Lateral inhibition shapes the oscillatory responses of the horseshoe crab's compound eye. G.H.Renninger (Dept. of Phys., Univ. of Guelph, Guelph, Ontario, Canada). *Biol. Cybern. (Germany)*, vol.46, no.2, p.119-27 (1983). The synchronized response of the compound eye of the horseshoe crab to uniform illumination arises from the integration of excitation with the strong lateral inhibition present in many specimens. At the higher levels of excitation, the steady production of nerve impulses by individual eccentric cells is often replaced by periodically recurring volleys of impulses. This behavior is shown to be the result of the temporal behavior of the post-synaptic potentials responsible for lateral inhibition. For a broad class of inhibitory potentials, a simple condition is established which separates potentials which permit volleys at high excitation levels from those which support only the steady production of impulses throughout the physiological range of excitations. (16 refs.)
- 78178 Retinotopic map on the visual cortex for eccentrically placed patterns: first noninvasive measurement. E.MacIin, Y.C.Okada, L.Kaufman, S.J.Williamson (Dept. of Psychology & Phys., New York Univ., New York, NY, USA). *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.410-19 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982). The observed cortical magnetic field evoked by a stimulus presented at various eccentricities in the visual field was interpreted as arising from current dipoles along the longitudinal fissure. The depth of the source increased as the eccentricity was increased, in agreement with the classical retinotopic map. (16 refs.)
- 78179 Visual processing in the leech central nervous system. E.L.Peterson (Dept. of Biology, McGill Univ., Montreal, Quebec, Canada). *Nature (GB)*, vol.303, no.5914, p.240-2 (19 May 1983). In animals with complex visual systems spatial contrast is enhanced by mutual inhibition between retinal neurones monitoring different fields. By analogy, if animals like leeches and some caterpillars, that have several simple (nonimage-forming) eyes aimed in different directions, are capable of rudimentary form detection, one might predict mutual antagonism between eyes monitoring different fields. In support of this prediction the author reports a paired interneurone in the central nervous system (CNS) of the leech which is stimulated by eyes on one side of the animal and inhibited by eyes on the other. There are striking parallels between these neurones and other integrating neurones, in particular those processing bilateral auditory input in crickets, suggesting that the visual system of the leech may be representative of a general class of sensory processing systems. - 78180 Progress in phototransduction. D.G.Stavenga, W.J.de Grip (Dept. of Biophys., Univ. of Groningen, Groningen, Netherlands). *Biophys. Struct. & Mech. (Germany)*, vol.9, no.4, p.225-30 (1983). Various aspects of the phototransduction mechanism have been highlighted during the Vth International Congress of Eye Research, held in Veldhoven, the Netherlands (from 5-8 October 1982). The correspondences and differences of phototransduction in both vertebrate and invertebrate photoreceptor cells were extensively discussed. The authors briefly review the present views. (48 refs.)
- 78181 Sensitizing pigment in the fly. K.Vogt, K.Kirschfeld (Max-Planck-Inst. fur Biologische Kybernetik, Tubingen, Germany). *Biophys. Struct. & Mech. (Germany)*, vol.9, no.4, p.319-28 (1983). The sensitizing pigment hypothesis for the high UV sensitivity in fly photoreceptors (R1-6) is further substantiated by measurements of the polarisation sensitivity in the UV. The quantum yield of the energy transfer from sensitizing pigment to rhodopsin was estimated by electrophysiological measurements of the UV sensitivity and the rhodomeric absorbance (at 490 nm) in individual receptor cells. The transfer efficiency is ≥ 0.75 in receptors with an absorbance in the rhodomer of 0.55-0.05. This result suggests that the sensitizing pigment is bound in some way to the rhodopsin. A ratio of two molecules of sensitizing pigment per one rhodopsin is proposed. (30 refs.)
- 78182 Bump latency distribution and bump adaptation of Limulus ventral nerve photoreceptor in varied extracellular calcium concentrations. H.Stieve, M.Bruns (Inst. fur Neurobiologie, KFA Julich GmbH, Julich, Germany). *Biophys. Struct. & Mech. (Germany)*, vol.9, no.4, p.329-39 (1983). Bumps were recorded as voltage signals following dim flashes of light. Bump amplitude and width did not much depend upon external Ca^{2+} -concentration. However, the distribution of bump latencies was strongly shifted to longer latencies and broadened more than two-fold when the external Ca^{2+} -concentration was lowered from 10 mmol/l to 0.25 mmol/l. Raising the external Ca^{2+} -concentration to 40 mmol/l had the opposite effect. A preadapting light flash caused shortening the narrowing of bump latency distribution similar to the effect of raised external Ca^{2+} -concentration. The bump amplitude was not correlated with the length of the latent period of the bump, indicating that the amplification processes determining the bump size are distinctly from those which determine the latent period. (21 refs.)
- 78183 Variations in the voltage response to single quanta of light in the photoreceptors of *Locusta migratoria*. J.Howard (Dept. of Neurobiology, Res. School of Biological Sci., Canberra, Australia). *Biophys. Struct. & Mech. (Germany)*, vol.9, no.4, p.341-8 (1983). Brief, dim flashes of light that produced on average only one response per three to six flashes were presented to dark-adapted locust photoreceptors. The amplitude, latency, and half-duration of the discrete voltage responses showed substantial variation. However all frequency distribution curves were single peaked, indicating that there is only one class of discrete voltage responses in the locust. Correlations between these parameters are low (accounting for less than 7% of the variance) but statistically significant. The low correlations suggest that different processes underlie the generation of amplitude, latency and duration of the bumps. (14 refs.)
- 78184 Light activated electrogenic Na^{+} - Ca^{2+} -exchange in fly photoreceptors: modulation by $\text{Na}^{+}/\text{K}^{+}$ -pump activity. E.Armon, B.Minke (Dept. of Physiology, Hebrew Univ.-Hadassah Medical School, Jerusalem, Israel). *Biophys. Struct. & Mech. (Germany)*, vol.9, no.4, p.349-57 (1983). The authors found recently that illumination of white-eyed *Musca* photoreceptors following application of ruthenium red (RR), (a known inhibitor of Ca^{2+} -uptake into intracellular organelles) induced a transient post-illumination-after depolarization (TA). They found that the TA depended strongly on Na^{+} and Ca^{2+} -gradients across the cell membrane suggesting that it arose from activation of electrogenic Na^{+} - Ca^{2+} -exchange. Since the magnitude of the TA was dependent on the Na^{+} -gradient, in this work the authors studied the effects of the $\text{Na}^{+}/\text{K}^{+}$ -pump, which controls the Na^{+} -gradient, on the TA. Increasing extracellular K^{+} -concentration which largely increased pump activity also increased the TA. Application of 100 μM ouabain, for a short time, depressed the TA considerably without causing any noticeable effect on the resting or the receptor potential. Only after longer exposure to ouabain, when the TA was totally depressed, where the resting and receptor potentials abolished by only a few strong light flashes. Trains of strong light pulses either facilitated or inhibited the TA depending on the degree of increase in internal Ca^{2+} -ions by light and on the activity of the $\text{Na}^{+}/\text{K}^{+}$ -pump. - 78185 Chromatic induction: responses of neurophysiological double opponent units?. A.Valberg, T.Seim (Dept. of Biophys., Univ. of Oslo, Oslo, Norway). *Biol. Cybern. (Germany)*, vol.46, no.2, p.149-58 (1983). Equations have been derived that improve the quantification of sensory equidistant colour and lightness differences. This has been achieved by a physiological approach involving nonlinear responses of cone mechanisms and two subsequent stages of linear opponent transformation to describe the Munsell System (Seim and Valberg, 1980). Using the formulation for the first opponent stage, colours induced into an achromatic center field, by a chromatic surround varying in purity, are shown to follow the same power function of the opponent coordinates for all hues. By analogy, a physiological model for colour coding and colour induction is offered. Double opponent neurones with spatially antagonistic, spectrally opponent and symmetric receptive fields constitute the units of the model. Colour induction is related to lateral excitation and colour differences to response differences of these units. (39 refs.)

78186 Human performance engineering. Looking through the user's eyes. R.W.Bailey. *Computerworld (USA)*, vol.17, no.18, p.ID1-6 (2 May 1983). Gives an introduction to visual perception as it relates to human performance engineering, for example in CRT or keyboard design. The importance of schema, or format, is emphasised. (no refs.)

78187 Perception of movement, the correlation model and the landing reaction of the flesh fly (Calliphoridae). L.Beghi (Seminario Matematico, Padova, Italy), N.Saviolo, E.Xausa, M.Zanforline. *Biol. Cybern. (Germany)*, vol.46, no.2, p.81-91 (1983). An analysis is made of the variations in sensitivity to movement in flesh flies (Calliphoridae) when placed in front of various fixed screens structured with black and white stripes. Two vertical bands moving from the centre to the periphery were projected onto these screens. The threshold of sensitivity to these bands was measured using the landing reaction. The results are compared with maximal values of theoretically predicted responses to movement, obtained using the model of nonlinear (2nd order) interaction between two pairs of neighbouring ommatidia (Reichardt, 1969) and taking into account the lateral inhibitory interaction between moving stripes and the background (4th order, *p*-order 2), as proposed by Reichardt and Poggio (1976). Experimental and theoretical results matched reasonably well except for screens with fixed alternate black and white stripes whose angular frequency ranged from 0.5 to 0.8 rad⁻¹, and for two screens of greatly reduced luminosity. (13 refs.)

87.34 AUDITION

78188 Studies of auditory evoked magnetic and electric responses: modality specificity and modelling. T.Tuomisto, R.Hari, T.Katila, T.Poutanen, T.Varpula (Dept. of Tech. Phys., Helsinki Univ. of Technol., Espoo, Finland). *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.471-83 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982). The sources of auditory evoked electric and magnetic responses were modelled with multiple current dipoles. The activity at the auditory cortices 2.6 cm beneath the skull, explains the observed *N*100m field distribution. An additional current source near the vertex is needed to explain the corresponding potential distributions. The locations of the current sources of *N*100m did not show any systematic dependence on the tonal frequency. (14 refs.)

78189 Determination of the normal threshold of hearing by bone conduction using different types of bone vibrators. I. K.Brinkmann, U.Richter. *Audiol. Akust. (Germany)*, vol.22, no.3, p.62-85 (May-June 1983). In German, English. In the frequency range from 125 Hz to 8000 Hz, on a large number of otologically normal persons, the bone-conduction hearing threshold was determined for three different types of bone vibrators. The mastoid and the forehead served as placement sites. The vibrotactile threshold which represents an upper level limit for an exact measurement of the bone-conduction hearing threshold, was also measured. The results show that for all bone vibrators which are in compliance with IEC specifications, the hearing threshold on the mastoid can be described by a single series of equivalent threshold force levels. Another series of values is valid for the hearing threshold on the forehead. At 125 Hz, the level range utilizable for measuring the bone conduction hearing threshold amounts only to about 14 dB (mastoid coupling) but increases towards higher frequencies. The differences between the thresholds of hearing by air and bone conduction of otologically normal persons show an approximately normal distribution with regard to the 0 dB value, differences exceeding ± 7.5 dB being still found in about 20% of the cases. (38 refs.)

78190 Music perception and elementary auditory sensations. II. E.Terhardt. *Audiol. Akust. (Germany)*, vol.22, no.3, p.86-96 (May-June 1983). In German, English. Between the essential features of music perception and the elementary hearing characteristics, interrelationships exist which in part prove to be surprisingly simple and clear. Such interrelationships have been found, among other things, to be of importance for the evaluation of the consequences of functional hearing disorders in the perception of music. The interrelationships applying to normally hearing persons are described, as far as they relate to the melodic and harmonic aspects of music. It is demonstrated that the sense of harmony is based on the psycho-acoustical fundamental principles of pitch perception and that the general pleasantness of sound (called sensory consonance) can be traced back to the three hearing attributes: roughness, sharpness and timbre. The interaction between harmony and pleasantness of sound results in the phenomenon of musical consonance and permits an adequate hearing-related description of many musical phenomena. (19 refs.)

78191 Speech competition effects on synthetic stop-vowel perception by normal and hearing-impaired listeners. S.M.Gordon-Salant (Dept. of Hearing & Speech Sci., Univ. of Maryland, College Park, MD, USA), F.L.Wightman. *J. Acoust. Soc. Am. (USA)*, vol.73, no.5, p.1756-65 (May 1983). A triadic comparisons task and an identification task were used to evaluate normally hearing listeners' and hearing-impaired listeners' perceptions of synthetic CV stimuli in the presence of competition. The competing signals included multitalker babble, continuous speech spectrum noise, a CV masker, and a brief noise masker shaped to resemble the onset spectrum of the CV masker. All signals and maskers were presented monotonically. Interference by competition was assessed by comparing multidimensional scaling solutions derived from each masking condition to that derived from the baseline (quiet) condition. Analysis of the effects of continuous maskers revealed that multitalker babble and continuous noise caused the same amount of change in performance, as compared to the baseline condition, for all listeners. CV masking changed performance significantly more than did brief noise masking, and the hearing-impaired listeners experienced more degradation in performance than normals. Finally, the velar CV maskers (g and k) caused significantly greater masking effects than the bilabial CV maskers (b and p), and were most resistant to masking by other competing stimuli. The results suggest that speech intelligibility difficulties in the presence of competing segments of speech are primarily attributable to phonetic interference rather than to spectral masking. Individual differences in hearing-impaired listeners' performances are also discussed. (21 refs.)

78192 Perception of static and dynamic acoustic cues to place of articulation in initial stop consonants. D.Kewley-Port, D.B.Pisoni (Dept. of Psychology, Indiana Univ., Bloomington, IN, USA), M.Studdert-Kennedy. *J. Acoust. Soc. Am. (USA)*, vol.73, no.5, p.1779-93 (May 1983). Two recent accounts of the acoustic cues which specify place of articulation in syllable-initial stop consonants claim that they are located in the initial portions of the CV waveform and are context-free. Stevens and Blumstein [ibid., vol.64, p.1358-1368 (1978)] have described perceptually relevant spectral properties of these cues as dynamic. Three perceptual experiments were conducted to test predictions derived from these accounts. Experiment 1 confirmed that acoustic cues for place of articulation are located in the initial 20-40 ms of natural stop-vowel syllables. Next, short synthetic CVs modeled after natural syllables were generated using either a digital, parallel-resonance synthesizer in experiment 2 or linear prediction synthesis in experiment 3. One set of synthetic stimuli preserved the static spectral properties proposed by Stevens and Blumstein. Another set of synthetic stimuli preserved the dynamic properties suggested by Kewley-Port. Listeners in both experiments identified place of articulation significantly better from stimuli which preserved dynamic acoustic properties than from those based on static onset spectra. Evidently, the dynamic structure of the initial stop-vowel articulatory gesture can be preserved in context-free acoustic cues which listeners use to identify place of articulation. (33 refs.)

78193 Reply to 'Comments on "Ear dominance and sequential interactions"' by E. William Yund. D.Deutsch (Center for Human Information Processing, Univ. of California, San Diego, La Jolla, CA, USA). *J. Acoust. Soc. Am. (USA)*, vol.73, no.5, p.1865-7 (May 1983). The author replies to comments by Yund (see ibid., vol.71, p.1287, 1982) on her original work (see ibid., vol.67, p.220, 1980), pointing out that the pitch assignment is in the octave corresponding to the frequency delivered to the dominant ear, that there is no valid basis for Yund's objection to the use of the 2AFC method, and that other arguments of his are erroneous. (7 refs.)

78194 Perceptual identification and discrimination of phase distortions. P.J.Bloom (Div. of Engng., Polytech. of Central London, London, England), D.Preis. Proceedings of ICASSP 83. IEEE International Conference on Acoustics, Speech and Signal Processing, Boston, MA, USA, 14-16 April 1983 (New York, USA: IEEE 1983), p.1396-9 vol.3 Experimental results on the audibility of phase distortion produced by minimum-phase 4kHz and 15 kHz anti-alias filters are reported. Numerous impulse response pairs with identical spectral magnitudes but linear-phase and minimum-phase responses were compared by five test subjects who listened dichotically on earphones. Group-delay distortion was doubled, progressively, until at least 67% mean correct discrimination was attained. At 4kHz, the phase distortion introduced by a cascade of two eighth-order Butterworth filter pairs was audible as was that from only a single pair of seventh-order elliptic filters. At 15kHz, the cascade of up to 4 pairs of seventh-order elliptic filters introduced no perceptible effects. Experimental details and several representative filter frequency and transient responses are included. (2 refs.)

78195 Development of a technique for high frequency audiometry. M.A.Krasner, K.N.Stevens, D.M.Green, S.H.Blumenthal (Bolt Beranek & Newman Inc., Cambridge, MA, USA). Proceedings of ICASSP 83. IEEE International Conference on Acoustics, Speech and Signal Processing, Boston, MA, USA, 14-16 April 1983 (New York, USA: IEEE 1983), p.1400-3 vol.3 Describes the development of a new technique for the assessment of hearing thresholds in the range 8-20 kHz. The authors describe a model that circumvents some major difficulties encountered by present audiometric methods at high frequencies and present measurements that validate that model. A technique that can provide accurate and reliable measurements is described and evaluated. (5 refs.)

87.36 SPEECH

(see also 43.70 Speech communication)

78196 The influence of inter- and intra-speaker tempo on fundamental frequency and palatalization. W.E.Cooper, C.Soaes, A.Ham, K.Damon (Dept. of Psychology, Harvard Univ., Cambridge, MA, USA). *J. Acoust. Soc. Am. (USA)*, vol.73, no.5, p.1723-30 (May 1983). A study was conducted to examine the influence of speaking rate and emphatic stress on patterns of fundamental frequency (*F*₀) and palatalization across word boundaries. Two groups of speakers, exhibiting characteristically fast versus slow speech, uttered preselected sentences at normal, fast, and slow rates. Acoustic analysis of *F*₀ showed somewhat higher *F*₀ peaks for characteristically fast speakers and for fast rates of speech. Emphatic stress was accompanied by a typical heightening of *F*₀ on the emphasised word and by a lowering of *F*₀ on a neighboring word. Palatalization across word boundaries was more frequent among characteristically fast speakers and at fast rates of speech. In addition, palatalization was more frequent in the absence of emphatic stress at the key site. The results for *F*₀ were discussed in terms of the influence vocal fold tension, while the results for palatalization were discussed in terms of the incompatibility of phonological processes of lengthening versus shortening as well as possible look-ahead restrictions. (15 refs.)

78197 Declination of fundamental frequency in speakers' production of parenthetical and main clauses. E.J.Kutik, W.E.Cooper (Harvard Univ., Cambridge, MA, USA), S.Boyce. *J. Acoust. Soc. Am. (USA)*, vol.73, no.5, p.1731-8 (May 1983). An experimental study was conducted to investigate fundamental frequency (*F*₀) contours in sentences with and without parenthetical clauses. Sentences consisted of a systematically lengthened parenthetical clause inserted between the subject noun phrase and the verb phrase of the main clause. The middle portion of the parenthetical was lengthened incrementally in each sentence to test the effects of sentence length on fundamental frequency contours of seven test sentences. Computer-aided measurements were made for: *F*₀ peaks of key stressed segments; duration of the main clause, parenthetical clause, and clause-final syllables within each; and pauses immediately preceding and following the parenthetical. Mean results demonstrate: (1) a drop in *F*₀ for the parenthetical clause, well below the main clause declination and forming a separate contour of declination; (2) a sharp rise in *F*₀ on return to the main clause; (3) no effect of longer parenthetical length on final segment durations of either the parenthetical or the main clause; and (4) no effect of increased parenthetical length on main clause duration or pause length. These results

suggest that parenthetical clauses are mentally programmed as independent constituents, but are subject to some of the same general declination constraints as main clauses. (23 refs.)

78198 Further evidence of acoustic invariance in speech production: the stop-glide contrast. M.Mack, S.E.Blumstein (Brown Univ., Providence, RI, USA).

J. Acoust. Soc. Am. (USA), vol.73, no.5, p.1739-50 (May 1983).

The authors have conducted a detailed comparative acoustic analysis of the labial stop and glide, [b] and [w], and they have attempted to identify an invariant acoustic property which can accurately distinguish stops and glides. To this end, they conducted three experiments. In experiment I, they undertook computer analysis of the labial stop [b] and the labial glide [w] as produced in five vowel contexts by two speakers. Results indicated that transition durations and formant frequencies often differed considerably in these two classes of sounds—and to a much greater extent than suggested in previous perception experiments. In experiment II the authors examined a measure of amplitude—unit energy. They calculated the degree of relative amplitude change occurring in the vicinity of the stop and glide release and found reliably larger changes in energy associated with the stop release than the glide release across vowel contexts and speakers. These changes seemed to provide an invariant property characterizing the stop-glide contrast. In experiment III the authors tested the generality of their claims by examining a new set of data consisting of the stops [d] and [g] and the glide [y]. Results of this experiment further supported their hypothesis. They have related their findings to a general theory of acoustic invariance in speech. (25 refs.)

78199 Some effects of speaking rate on the production of /b/ and /w/. J.L.Miller (Dept. of Psychology, Northeastern Univ., Boston, MA, USA), T.Baer.

J. Acoust. Soc. Am. (USA), vol.73, no.5, p.1751-5 (May 1983).

One of the acoustic properties distinguishing the syllable-initial stop consonant /b/ from the semivowel /w/ is the duration of the initial formant transitions; syllables beginning with /b/ have shorter transitions than those beginning with /w/. This experiment investigated the way in which the transition durations of /b/ and /w/ change as a function of speaking rate by examining tokens of /ba/ and /wa/ produced by four male speakers. At any given speaking rate the /wa/ transitions were, on average, longer than the /ba/ transitions, although pooled across rates, the distributions of transition duration for /ba/ and /wa/ were overlapping. In addition, the magnitude of the difference between average /ba/ and /wa/ transition durations increased with decreases in speaking rate. This is because as rate of speech decreased so that syllable duration increased, there was little change in the initial transition duration of /ba/, but a considerable increase in the initial transition duration of /wa/. Given the overall pattern of results, the transition duration that could optimally distinguish /ba/ from /wa/ was not constant, but increased with syllable duration. This is in accord with Miller and Liberman's (1979) finding that when listeners identify /ba/ and /wa/ on the basis of transition duration, they do so in relation to the duration of the syllable. (15 refs.)

78200 A preliminary model of subjective voice quality. G.J.Boggs (GTE Labs., Waltham, MA, USA).

Proceedings of ICASSP 83. IEEE International Conference on Acoustics, Speech and Signal Processing, Boston, MA, USA, 14-16 April 1983 (New York, USA: IEEE 1983), p.1404-6 vol.3

Psychophysical scaling is a popular methodology for subjective speech quality assessment. Unfortunately, scaling techniques are not bias-free measurements. A conceptual model is developed, based on the theory of signal detectability and the internal-noise model. The implications of the conceptual model for speech quality assessment are discussed. (9 refs.)

78201 Vibrotactile identification of vowels. B.G.Green, J.C.Craig, A.M.Wilson, D.B.Pisoni, R.P.Rhodes (Dept. of Psychology, Indiana Univ., Bloomington, IN, USA).

J. Acoust. Soc. Am. (USA), vol.73, no.5, p.1766-78 (May 1983).

The ability of subjects to identify vowels in vibrotactile transformations of consonant-vowel syllables was measured for two types of displays: a spectral display (frequency by intensity), and a vocal tract area function display (vocal tract location by cross-sectional area). Both displays were presented to the fingertip via the tactile display of the Optacon transducer. In the first experiments the spectral display was effective for identifying vowels in /b-V/ context when as many as 24 or as few as eight spectral channels were presented to the skin. However, performance fell when the 12- and 18-channel displays were reduced in size to occupy 1/2 or 1/3 of the 24-row tactile matrix. The effect of reducing the size of the display was greater when the spectrum was represented as a solid histogram ('filled' patterns) than when it was represented as a simple spectral contour ('unfilled' patterns). Spatial masking within the filled pattern was postulated as the cause for this decline in performance. Another experiment measured the utility of the spectral display when the syllables were produced by multiple speakers. The resulting increase in response confusions was primarily attributable to variations in the tactile patterns caused by differences in vocal tract resonances among the speakers. The final experiment found an area function display to be inferior to the spectral display for identification of vowels. The results demonstrate that a two-dimensional spectral display is worthy of further development as a basic vibrotactile display for speech. (40 refs.)

87.40 BIOMAGNETISM

(inc. magnetocardiography)

78202 The magnetic field produced by the conduction system of the human heart. J.L.Patrick, D.W.Hess, H.J.Tripp, D.E.Farrell (Dept. of Phys., Case Western Reserve Univ., Cleveland, OH, USA).

Nuovo Cimento D (Italy), vol.2D, ser.1, no.2, p.255-65 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).

The authors have exploited the spatial resolution of the magnetic sensor to provide numerical estimates of the atrial contribution to magnetic fields recorded just prior to ventricular depolarisation. The contribution is found to be small, strengthening the authors' original interpretation that such fields originate mostly in the conduction system of the heart. (17 refs.)

78203 Atrial activity during the PR segment of the MCG. M.Leifer (Dept. of Phys., Stanford Univ., Stanford, CA, USA), N.Capos, J.Griffin, J.Wikswa, Jr.

Nuovo Cimento D (Italy), vol.2D, ser.1, no.2, p.266-79 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).

Sloping signals were observed in the PR segment of normal magnetocardiograms recorded from five dogs. Larger ramps were observed after first-degree AV nodal blockade was induced pharmacologically, and complete atrial repolarisation was observed following isolated atrial contractions in two animals with second-degree block. These ramps, ranging up to 6.7 pT in size and arising from the atria, may complicate magnetic detection of His-Purkinje activity. (10 refs.)

78204 Magnetic measurements and modelling for the investigation of the human-heart conduction system. R.R.Fenici (Unita Biomagnetica, Univ. Cattolica, Roma, Italy), G.L.Romani, R.Leoni.

Nuovo Cimento D (Italy), vol.2D, ser.1, no.2, p.280-90 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).

Since 1980, systematic investigations of the activity of the His-Purkinje system (HPS) by the biomagnetic method have been reported on both normal subjects and patients affected by different kinds of conduction disturbances. A first attempt to interpret the experimental results by means of a theoretical model satisfactorily accounted for the measured 'ramp' patterns. Moreover, a good temporal coincidence was observed between magnetic signals and invasively recorded His bundle electrograms. An alternative explanation of the 'ramp' pattern, in terms of atrial repolarisation, has been recently proposed on the basis of animal experimental investigation. In order to try to solve this problem, the authors have carried out a twofold approach: a new second-order gradiometer, specifically designed for HPS activity investigation has been successfully set up and tested; it provides a sensitivity of 20 fT/√Hz in the band width of interest ((0.5-300) Hz). Second, a new model based on a closer correspondence to anatomical features of the HPS has been developed. This model provides well-defined patterns which are in quite good agreement with experimental results. (15 refs.)

78205 The influence of inhomogeneities on the cardiac-magnetic-field distribution. M.J.Peters, M.J.M.Swennenhuis, A.van Oosterom, J.J.Wevers-Henke (Dept. of Tech. Phys., Twente Univ. of Technol., Enschede, Netherlands).

Nuovo Cimento D (Italy), vol.2D, ser.1, no.2, p.324-39 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).

Numerical computations were performed on the magnetic field generated by the heart during ventricular depolarization. The purpose of this study was to investigate the contribution of inhomogeneities in the volume conductor to the total field and to establish the influence of gradiometers as used in experimental recordings. (22 refs.)

78206 On the influence of the volume conductor in magnetocardiography: an experimental approach. I.R.Eghrari, E.Costa Monteiro, P.Costa Ribeiro, J.P.von der Weid (Dept. de Fisica, Pontificia Univ. Catolica do Rio de Janeiro, Rio de Janeiro, Brazil).

Nuovo Cimento D (Italy), vol.2D, ser.1, no.2, p.346-55 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).

To study the effect of the volume conductor geometry on the MCG, experiments using isolated rabbit hearts were done. An increase of the magnetic signal when increasing the volume conductor's size was observed. The results are discussed in terms of using a fixed-origin current dipole and a voltage source model for the heart. (6 refs.)

78207 First magnetic measurements of action currents in isolated cardiac Purkinje fibers. J.P.Wikswa, J.P.Barach, S.C.Gundersen (Dept. of Phys. & Astron., Vanderbilt Univ., Nashville, TN, USA).

Nuovo Cimento D (Italy), vol.2D, ser.1, no.2, p.368-78 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).

Presents the first measurements of the magnetic field associated with the action potential in a bundle of isolated cardiac Purkinje fibers. These findings demonstrate the feasibility of using magnetic techniques to measure the axial current in a bundle of spontaneously active cardiac cells. (10 refs.)

78208 Inferences concerning anatomy and physiology of the human brain based on its magnetic field. Y.C.Okada (Dept. of Psychology, New York Univ., New York, NY, USA).

Nuovo Cimento D (Italy), vol.2D, ser.1, no.2, p.379-409 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).

Research in the evoked magnetic field reported in the last two years is reviewed. The studies have shown that the magnetic technique may be used (1) to reveal complementary aspects of the current sources common to evoked potential, (2) to identify the organization of the cerebral cortex and subcortical areas of the brain, and (3) to measure functional properties of the active neural areas whose locations are identified. (58 refs.)

78209 Neuromagnetic localization of two components of the transient visual evoked response to patterned stimulation. F.Richer, D.S.Barth, J.Beatty (Dept. of Psychology, Univ. of California, Los Angeles, CA, USA).

Nuovo Cimento D (Italy), vol.2D, ser.1, no.2, p.420-8 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).

Corresponding electrical and magnetic components of the brain's visual evoked response peaking at 120 and 180 ms poststimulus are examined. Results show that both magnetic components are localized in the superficial occipital cortex tangential to the scalp. The distribution of M120 suggests that the generators for the electrical and magnetic components are related, but the electrical field record is an elaborate modification of that produced by the source. (8 refs.)

78210 Somatosensory evoked magnetic fields: mappings and the influence of the stimulus repetition rate. D.Teszner, R.Hari, P.Nicholas, T.Varpula (Hopital Ambroise Pare, Boulogne, France).

Nuovo Cimento D (Italy), vol.2D, ser.1, no.2, p.429-37 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).

Somatosensory evoked magnetic fields were compared with corresponding electric scalp potentials in order to study their neural sources. Mappings of the magnetic responses showed activity at the primary and secondary somatosensory cortices. Additional sources besides these areas seem to be involved in the generation of the somatosensory vertex scalp potentials. (15 refs.)

78211
Some tentative model considerations based on experimental neuro-magnetic data.
K.Saermark (Phys. Lab. I, Tech. Univ. of Denmark, Lyngby, Denmark).
Nuovo Cimento D (Italy), vol.2D, ser.1, no.2, p.438-59 (March-April 1983).
(Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).

Presents some tentative model considerations, based on the concept of an equivalent current dipole to account for observed auditory evoked responses, with the aim of attempting a comparison of variations in amplitude and latency with calculations based on Rall's (1962) greatly simplified nerve model. A phenomenological analysis of experimental data on the late, auditory evoked magnetic field from the human auditory cortex is presented. The emphasis is placed on relations between signal properties (e.g. amplitude and latency) and between signal properties and stimulus properties (e.g. amplitude/latency and relative frequency glide $\Delta f/f$ for a frequency glide stimulus) rather than on questions related to the location of the equivalent current dipole, e.g. the tonotopic organization discussed by Eiberling et al. (1982) and by Romani et al.(1982). Some results of a numerical calculation based on a linear-cable model are presented and compared with experimental results. (50 refs.)

78212
Auditory evoked magnetic fields: a replication, with comments on the magnetic P50 analog.
J.T.Zimmerman, M.Reite (School of Medicine, Univ. of Colorado, Denver, CO, USA), J.E.Zimmerman, J.Edrich.
Nuovo Cimento D (Italy), vol.2D, ser.1, no.2, p.460-70 (March-April 1983).
(Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).

Auditory evoked magnetic fields (AEFs) and EEG auditory evoked potentials (AEPs) were recorded from left and right auditory cortical regions of 12 normal adult subjects. The magnetic sensor was a figure-eight SQUID gradiometer with a 4 cm baseline oriented so as to be maximally sensitive to a current dipole oriented normal to the Sylvian fissure. Stimuli were 100 ms long 1 kHz tone pips with a modal interstimulus interval of 700 ms delivered at sound pressure levels of 40, 60, 80 and 100 dB. AEF amplitude was found to be related to stimulus intensity in a quadratic fashion, AEP amplitude in a linear fashion. AEFs were of larger amplitude in response to contralateral as compared to ipsilateral stimulation. AEPs did not exhibit such a relationship. In a second experiment right-hemisphere AEFs and AEPs in response to contralateral ear tone stimulation in these 12 subjects were combined with similar previous data from 24 subjects, providing a total of 36 subjects, to examine the comparability of the AEP P50 wave form and the AEF P50 analog. The latency of the P50 was found to decrease as a function of increasing stimulus intensity for both AEFs and AEPs, and the P50 latency was consistently shorter in magnetic compared to potential recordings. (14 refs.)

87.45 BIOMECHANICS, BIORHEOLOGY, BIOLOGICAL FLUID DYNAMICS

78213
Control of muscle contractile force through indirect high-frequency stimulation.
M.Solomonow (Dept. of Engng. Systems, Univ. of California, Los Angeles, CA, USA), E.Eldred, J.Lyman, J.Foster.
Am. J. Phys. Med. (USA), vol.62, no.2, p.71-82 (April 1983).

With a view to possible application in an orthotic device, study was made of the attenuation of background, indirectly induced muscle tetanus produced by superimposing high-frequency electrical stimulation of the muscle nerve. The effects of varying duration, current and frequency of pulses of the stimulus were outlined, and it was concluded that optimal application might be obtained using a stimulus frequency of 500 Hz, a pulse duration of 50 μ sec, and varying the frequency to grade the effect. (14 refs.)

78214
Heart rate variability and blood pressure oscillations in diabetics with autonomic neuropathy.
T.J.Van Den Akker, A.S.M.Koelman (Dept. of Medical Phys., Free Univ., Amsterdam, Netherlands), L.A.H.Hogenhuis, O.Rompelman.
Automedica (GB), vol.4, no.4, p.201-8 (1983).

The frequency of the spontaneous narrow band blood pressure oscillations in both groups of diabetics with autonomic neuropathy and healthy persons was compared using the power spectrum of the heart rate variability signal. The shift in the centre frequency of the narrow band oscillation might provide a method of assessing early sympathetic nervous disorders in diabetics. (34 refs.)

78215
Beat-to-beat variability of heart interval and blood pressure.
R.W.De Boer, J.M.Karemaker, J.Strackee (Univ. of Amsterdam, Amsterdam, Netherlands).
Automedica (GB), vol.4, no.4, p.217-21 (1983).

A set of three mathematical equations is proposed to model the beat-to-beat properties of the fast blood pressure regulation system. The equations are based on the following physiological considerations: (1) The length of the RR-interval is dependent on the systolic pressure (baroreflex). (2) The pulse pressure is dependent on the length of the preceding interval (due to the restitution properties of the myocardium and to Starling's law). (3) During diastole the pressure decay can be described by a Windkessel equation. As preliminary results the authors found that blood pressure data from hypertensive patients which showed respiratory sinus arrhythmia agreed well with Eqs. (1) and (3), and that data from a patient with atrial fibrillation agreed with Eqs. (2) and (3). (12 refs.)

78216
Micromotion in smooth muscle related to circulation control: a hypothesis.
W.A.Van Duyl (Dept. of Biological & Medical Phys., Erasmus Univ. Rotterdam, Rotterdam, Netherlands).
Automedica (GB), vol.4, no.4, p.233-9 (1983).

The so-called 10-second-rhythm in blood pressure is considered. At the moment the prevailing explanation of this rhythm is that it comes from the overall blood pressure control, i.e. it is generated by an oscillator of the global type. By taking into account features of smooth muscle the author presents an alternative view concerning the origin of this rhythm, in which oscillatory phenomena of the local type are involved. (18 refs.)

78217
On the effect of the concentration profile of red cells on blood flow in the artery with stenosis.
J.Perkkio (Dept. of Medical Phys., Univ. of Helsinki, Helsinki, Finland), R.Keskinen.
Bull. Math. Biol. (GB), vol.45, no.2, p.259-67 (1983).

The effects of the viscosity-concentration dependence and of the concentration profile on blood flow through a vessel with stenosis have been studied. The flow resistance and the wall shear stress have been found to be smaller than in the two-fluid model with constant viscosities (Shukla et al., 1980). (14 refs.)

78218
The information transmitted at final position in visually triggered forearm movements.
B.Sakitt, F.Lestienne, T.A.Zeffiro (Dept. of Psychology, MIT, Cambridge, MA, USA).
Biol. Cybern. (Germany), vol.46, no.2, p.111-18 (1983).

Visually triggered forearm movements are analyzed by an information theory approach. Human subjects made smooth movements which were characterized by moderate speeds, ranging about 100 degrees per second, by continuity in the position and velocity traces, and attainment of final average EMG levels before completion of the movement. The authors calculate the information transmitted by final position, biceps EMG, triceps EMG, and the ratio of the EMGs. (18 refs.)

78219
Physical principles for economies of skilled movements.
W.L.Nelson (Bell Labs., Murray Hill, NJ, USA).
Biol. Cybern. (Germany), vol.46, no.2, p.135-47 (1983).

Presents some elementary principles regarding constraints on movements, which may be useful in modeling and interpreting motor control strategies for skilled movements. Movements which are optimum with respect to various objectives, or 'costs', are analyzed and compared. The specific costs considered are related to movement time, distance, peak velocity, energy, peak acceleration, and rate of change of acceleration (jerk). The velocity patterns for the various minimum cost movements are compared with each other and with some skilled movement patterns. The concept of performance trade-offs between competing objectives is used to interpret the distance-time relationships observed in skilled movements. Examples of arm movements during violin bowing and jaw movements during speech are used to show how skilled movements are influenced by considerations of physical economy, or 'ease', of movement. (16 refs.)

78220
Motor reaction time and stereotyped pattern of the EMG activities in ballistic elbow extension.
H.Nagasaki, N.Irie, R.Nakamura (Inst. of Rehabilitation Medicine, Tohoku Univ., Sendai, Japan).
Electromyography & Clin. Neurophysiol. (Belgium), vol.23, no.3, p.167-81 (March-April 1983).

Motor reaction time (MT) of the triceps brachii, an interval from the initiation of the EMG activities to the overt motor response, was examined for a ballistic elbow extension in a horizontal plane under conditions of different initial joint angles of the elbow and external loads. MT was independent of joint angles over a range from 120° to 30° flexion and increased linearly from 35 to 70 msec with the external load from 0 to 2.5 kg. The rectified and the added EMG activities exhibited a stereotyped pattern during first 70 msec, which was not affected by the change of initial joint angle or external load. The pattern was also independent from the timing of the initiation of the actual movement. These results were interpreted as follows: (1) MT represents a time necessary to develop muscular tension for the movement initiation, and the rate of the tension development is controlled to be constant over a wide range of joint angles, (2) under loading, the rate still remains unchanged, but MT increases because greater tension is required for the movement initiation against the load, (3) the stereotyped EMG pattern gives evidence that an early stage of ballistic movement is centrally preprogrammed and it follows that the timing of the movement initiation is also under control of the motor centre. (20 refs.)

78221
A theoretical model of absorption of gases by the bronchial wall.
M.R.Davidson (Appl. Maths. & Computing Div., Australian Atomic Energy Comm. Res. Establ., Lucas Heights, Sutherland, Australia), R.C.Schroter.
J. Fluid Mech. (GB), vol.129, p.313-35 (April 1983).

The pattern of dispersion and uptake of an inhaled slug of tissue-soluble gas is examined within a branching model of the bronchial airways of the human lung, considered as an assembly of segments from infinitely long, straight rigid tubes with absorbing walls of finite thickness. The model is based on the first three (time-dependent) spatial moments of the solute distribution in such tubes, determined by the Aris method of moments. Poiseuille flow in each airway is assumed, and the solute distribution is taken to be initially zero in the tissue and radially uniform in the gas. First, the time dependence of axial velocity and mixing coefficient of the advancing solute in infinitely long tubes is shown and the mechanisms responsible are discussed. Transit times, uptake,

uptake efficiency and mixing coefficient predicted from the model are then shown for different flow rates and solubilities, as functions of the generation of branching. As is expected, greater penetration is found for lower-solubility gases. (21 refs.)

78222 A hydrodynamic study of vascular lesion. M.Kawaguti, A.Hamano (Dept. of Phys., Keio Univ., Yokohama, Japan). *Proc. Indian Acad. Sci. Eng. Sci.*, vol.5, pt.2, p.85-105 (July 1982). [received: April 1983]

In order to search for the origin of vascular lesion from the hydrodynamic point of view, the viscous flows in a constricted channel and in a channel with a branch are studied numerically. The results obtained show the importance of the temporal variation of shearing stress on the wall. (13 refs.)

78223 Constructing a mathematical model for myocardial infarction. F.I.Obratsov, G.G.Avtandilov, A.S.Vol'mir (Central Inst. for Improvement of Physicians, USSR).

Sov. Phys.-Dokl. (USA), vol.27, no.8, p.655-7 (Aug. 1982). Translation of: *Dokl. Akad. Nauk SSSR*, vol.265, no.4-6, p.1090-3 (Aug. 1982). [received: May 1983]

Considers myocardial infarction as resulting from a catastrophe in the cardiovascular system, accompanied by abrupt changes in the blood supply to the heart; this study makes use of the general mathematical theory of catastrophes and is correlated with studies on the stability of the vascular membranes. The article is devoted to consideration of the most important mechanical effects associated with changes in the coronary blood flow in the period preceding the development of the myocardial infarct. (15 refs.)

78224 Modeling systolic mitral valve motion: a tool for clarifying mitral valve prolapse. J.F.Hunter (Dept. of Veterinary Physiology & Pharmacology, Texas A&M Univ., College Station, TX, USA), D.P.Seaton, W.M.Lively, G.E.Miller, D.L.Stoner.

Texas J. Sci. (USA), vol.35, no.1, p.5-36 (March 1983). A dynamic model of the human heart's mitral valve motion during systole is presented. This model includes a description of the geometrical interrelationships between components of the mitral apparatus, namely mitral valve leaflets, annulus, chordae tendineae, papillary muscles, and left ventricle. The biomechanical properties of the mitral valve leaflets and chordae tendineae and the contractile nature of the annulus, papillary muscles and left ventricle are considered. Mitral valve profile/position is described for selected properties of model components. (85 refs.)

78225 Fluid mechanics of green plants. R.H.Rand (Dept. of Theoretical & Appl. Mech., Cornell Univ., Ithaca, NY, USA).

In book: *Annual review of fluid mechanics*. Vol.15, M.Van Dyke, J.V.Wehausen, J.L.Lumley [Ed.], p.29-45. Palo Alto, CA, USA: Annual Reviews (1983), 534 pp. [0 8243 0715 1]

Studies of each of the parts of a plant have involved special fluid mechanics problems based on the particular physiological function and geometry. The article introduces the reader to the concepts and problems that are unique to the fluid mechanics of plants and reviews the mathematical literature on this subject. (56 refs.)

87.50 BIOLOGICAL EFFECTS OF RADIATIONS

(inc. effects of fields)

78226 Relationship between field strength and arousal response in mice exposed to 60-Hz electric fields. R.S.Rosenberg, P.H.Duffy, G.A.Sacher, C.F.Ehret (Div. of Biological & Medical Res., Argonne National Lab., Argonne, IL, USA).

Bioelectromagnetics (USA), vol.4, no.2, p.181-91 (1983). White-footed mice, *Peromyscus leucopus*, were exposed to 60-Hz electric fields to study the relationship between field strength and three measures of the transient arousal response previously reported to occur with exposures at 100 kV/m (see R.S. Rosenberg et al., ibid., vol.2, p.291-303, 1981). Five groups of 12 mice each were given a series of four 1-h exposures, separated by an hour, with each group exposed at one of the following field strengths: 75, 50, 35, 25, and 10 kV/m; 8 additional mice were sham-exposed with no voltage applied to the field generator. The first exposure produced immediate increases in arousal measures, but subsequent exposures had no significant effect on any measure. These arousal responses were defined by significant increases of gross motor activity, carbon dioxide production, and oxygen consumption, and were frequently recorded with field strengths of 50 kV/m or higher. The results show that the amplitude of the transient arousal response is related to the strength of the electric field, but different measures of arousal may have different relationships to field strength. (17 refs.)

78227 Effects of high-intensity 60 Hz fields of bone growth. C.F.Walker (Dept. of Biomed. Engng., Tulane Univ., New Orleans, LA, USA), D.L.Seitelman, J.H.McElhaney, S.P.Mullen, B.Hagadorn, Yeb Jo Seto.

J. Bioelectr. (USA), vol.1, no.3, p.339-49 (1982). As part of an ongoing investigation of physiologic effects of high-voltage power frequency electric fields, femora from 55 adult rats which had been conceived, born, and raised in an 80 kV/m, 60 Hz unperturbed field were excised and studied. Specimens from 49 sham-exposed animals were also characterized in this double-blind study. Parameters evaluated were body weight, wet and dry bone weights, bone length, specific gravity, and various ratios of these parameters. Results from a statistical analysis indicated that chronic field exposure enhanced growth in the long bones, causing increased length and mass. (21 refs.)

78228 Dose-effect relationship for 14.5 MeV (d+T) neutron-induced chromosome aberrations in human lymphocytes irradiated in a man phantom. M.Bauchinger (Abteilung für Strahlenbiologie, Cyto genetics, Neuberger, Germany), H.Kuhn, J.Dresp, E.Schmid, S.Streng.

Int. J. Radiat. Biol. (GB), vol.43, no.5, p.571-8 (May 1983). Human lymphocytes were irradiated with 14.5 MeV (d+T) neutrons at the positions sternal, retrosternal, liver and gonads of a waterfilled Plexiglas man phantom of 37°C. After BUDR treatment of lymphocyte cultures and FPG-staining of metaphases, exclusively first post-irradiation divisions (M_1 -cells) were analysed. A regression analysis was carried out by means of a weighted least-squares method. Dose-effect relations of dicentric and acentric could be fitted by the linear-quadratic model. A comparison of the dose-effect curves established with either conventional or FPG-staining techniques revealed statistically significant differences. The M_1 -evaluation yielded about 46 per cent more dicentrics and about 37 per cent more acentrics. The consequences of these results are discussed in relation to the application of chromosome analysis in 'biological dosimetry'. (24 refs.)

78229 DNA replication and repair in human cells exposed to thermal neutrons. M.D.Ford (Dept. of Biochem., Univ. of Queensland, Brisbane, Australia), M.F.Lavin, D.Wilson.

J. Radiat. Res. (Japan), vol.23, no.4, p.423-30 (Dec. 1982). [received: May 1983]

The degree of inhibition of DNA replication and the level of DNA repair synthesis induced by thermal neutron irradiation was determined in human lymphoblastoid cell lines. Dose response experiments revealed that, when compared with equivalent doses of ^{60}Co - γ -irradiation, thermal neutrons gave rise to similar levels of inhibition of DNA replication but induced relatively low levels of DNA repair synthesis. The amount of repair synthesis after exposure of cells to thermal neutrons, was about ten-fold lower than that observed after γ -radiation. Reasons for this difference are discussed in terms of the type and incidence of damage induced by thermal neutrons. (17 refs.)

78230 Testicular function of rats following exposure to microwave radiation. R.M.Lebowitz, L.Johnson (Univ. of Texas Health Sci. Center, Dallas, TX, USA).

Bioelectromagnetics (USA), vol.4, no.2, p.107-14 (1983).

Male Sprague-Dawley rats were exposed for 6 h per day for nine days to pulse-modulated microwave radiation (1.3 GHz, at 1- μs pulse width, 600 pulses per second). Exposures were carried out in cylindrical waveguide sections at a mean dose rate of 6.3 mW/g; sham controls were treated similarly and received no irradiation. At time periods corresponding to 0.5, 1.0, 2.0, and 4.0 cycles of the seminiferous epithelium, groups of four sham-irradiation and four irradiated rats were killed and the testes removed for analysis. Net mass of the testes, epididymides, and seminal vesicles; daily sperm production (DSP) per testis and per gram of testis; sperm morphology; and the number of epididymal sperm were determined. There were no statistically significant differences between the sham-irradiated and irradiated groups with respect to any measured variable. In a group of seven surrogate animals of similar body mass, the dose rate of 6.3 mW/g caused a net change in body temperature (via rectal probe) of 1.5°C. (20 refs.)

78231 Effects of microwaves and hyperthermia on capping of antigen-antibody complexes on the surface of normal mouse B lymphocytes. M.F.Sultan, C.A.Cain (Dept. of Electrical Engng., Univ. of Illinois, Urbana, IL, USA), W.A.F.Tompkins.

Bioelectromagnetics (USA), vol.4, no.2, p.115-22 (1983).

Normal mouse B lymphocytes were tested for the ability to cap plasma membrane antigen-antibody complexes following exposure to 2.45-GHz continuous wave microwaves at power densities up to 100 mW/cm² (45 W/kg specific absorption rate), at 37, 41, and 42.5°C. After a 30-minute treatment, the irradiated cells and the nonirradiated controls were tested for capping by the direct immunofluorescence technique. First, the cells were incubated for nine minutes at 37°C with fluorescein isothiocyanate-conjugated goat anti-mouse immunoglobulin. After fixing and washing, the percentage of capped cells was determined under a fluorescence microscope. The results show that for the nonirradiated controls, capping is reduced from 90% at 37°C, to 52% at 41°C, to less than 5% for cells that were pretreated at 42.5°C. There was no significant difference between the microwave-treated cells and the controls when both were maintained at the same temperature. In another experiment, there was no significant difference in the percentage of capping between controls and cells that were exposed to microwave radiation during capping, when the temperature in both preparations was kept at 38.5°C. The results demonstrate that B-lymphocyte capping is sensitive to temperature in the range that is proposed for use in tumor therapy. (26 refs.)

78232 Effects of microwave exposure on the hamster immune system. I. Natural killer cell activity. H.K.Yang (Dept. of Pathobiology, Univ. of Illinois, Urbana, IL, USA), C.A.Cain, J.Lockwood, W.A.F.Tompkins.

Bioelectromagnetics (USA), vol.4, no.2, p.123-39 (1983).

Hamsters were exposed to repeated or single doses of microwave energy and monitored for changes in core body temperature, circulating leukocyte profiles, serum corticosteroid levels, and natural killer (NK) cell activity in various tissues. NK cytotoxicity was measured in a ^{51}Cr -release assay employing baby hamster kidney (BHK) targets or BHK infected with herpes simplex virus. Repeated exposure of hamsters at 15 mW/cm² for 60 min/day had no significant effect on natural levels of spleen-cell NK activity against BHK targets. Similarly, repeated exposure at 15 mW/cm² over a 5-day period had no demonstrable effect on the induction of spleen NK activity by vaccinia virus immunization, that is, comparable levels of NK were induced in untreated and microwave-treated animals. In contrast, treatment of hamsters with a single 60-min microwave exposure at 25 mW/cm² caused a significant suppression in induced spleen NK activity. A similar but less marked decrease in spleen NK activity was observed in sham-exposed animals. (33 refs.)

78233 Effects of microwave exposure on the hamster immune system. II. Peritoneal macrophage function. G.Rama Rao, C.A.Cain, J.Lockwood, W.A.F.Tompkins (Dept. of Electrical Engng., Univ. of Illinois, Urbana, IL, USA).

Bioelectromagnetics (USA), vol.4, no.2, p.141-55 (1983). For pt.1 see *ibid.*, vol.4, p.123-39 (1983). Acute exposure of hamsters to microwave energy (2.45 GHz; 25 mW/cm² for 60 min) resulted in activation of peritoneal macrophages that were significantly more viricidal to vaccinia virus as compared to sham-exposed or normal (minimum-handling) controls. Macrophages from microwave-exposed hamsters became activated as early as 6 h after exposure and remained activated for up to 12 days. The activation of macrophages by microwave exposure paralleled the macrophage activation after vaccinia virus immunization. Activated macrophages from vaccinia-immunized hamsters did not differ in their viricidal activity when the hamsters were microwave or sham-exposed. Exposure for 60 min at 15 mW/cm² did not activate the macrophages while 40 mW/cm² exposure was harmful to some hamsters. Average maximum core temperatures in the exposed (25 mW/cm²) and sham groups were 40.5°C (± 0.35 SD) and 38.4°C (± 0.5 SD), respectively. In vitro heating of macrophages to 40.5°C was not as effective as in vivo microwave exposure in activating macrophages to the viricidal state. (22 refs.)

78234 Immunological effects of amplitude-modulated radio frequency radiation: B lymphocyte capping. M.F.Sultan, C.A.Cain (Dept. of Electrical Engng., Univ. of Illinois, Urbana, IL, USA), W.A.F.Tompkins. *Bioelectromagnetics (USA)*, vol.4, no.2, p.157-65 (1983).

B lymphocytes collected from normal ICR Swiss mouse spleens were exposed in vitro in a Crawford cell to 147-MHz radiofrequency (RF) radiation, amplitude modulated by a 9-, 16-, or 60-Hz sine wave. The power densities ranged between 0.11 and 48 mW/cm². The irradiated samples and the controls were maintained at 37°C or 42°C, with temperature variations less than 0.1°C. Immediately after a 30-minute exposure, the distribution of antigen-antibody (Ag-Ab) complexes on the cell surface was evaluated at 37°C by immunofluorescence. Under normal conditions (37°C, no RF), Ag-Ab complexes are regrouped into a polar cap by an energy-dependent process. The results demonstrate that the irradiated cells and the nonirradiated controls capped Ag-Ab complexes equally well after exposure at 37°C. Capping was equally inhibited at 42°C in both the controls and irradiated cells. No statistically significant differences in capping were observed between the RF-exposed and control samples at any of the modulation frequencies and power densities employed as long as both preparations were maintained at the same temperature. (17 refs.)

78235 A mathematical model of the effects of light on the eclosion rhythm of the fruit fly *Drosophila pseudoobscura*. R.J.Schilling (ECE Dept., Clarkson Coll., Potsdam, NY, USA). *Bull. Math. Biol. (GB)*, vol.45, no.2, p.169-92 (1983).

A mathematical formulation useful in characterizing the effects of light on the pupal eclosion rhythm of the fruit fly *Drosophila pseudoobscura* is presented. It is based upon the premise that the underlying pacemaker oscillator behaves in a manner analogous to a customized version of a phase-locked loop circuit. Theoretical analyses supplemented with numerical simulations reveal that this phase-locked loop approach yields a concise mathematical characterization which is quite comprehensive in its scope, yet surprisingly accurate in the detail with which it can be used to successfully predict observed experimental results. (30 refs.)

78236 Laser induced visual pigment conversions in fly photoreceptors measured in vivo. B.Kruizinga, R.L.Kamman, D.G.Stavenga (Dept. of Biophys., Rijksunivers. Groningen, Groningen, Netherlands). *Biophys. Struct. & Mech. (Germany)*, vol.9, no.4, p.299-307 (1983).

The photochemical cycle of fly visual pigment was studied in vivo with laser methods. Two pulsed dye lasers were used, one delivering the visual pigment converting flash and the other testing the pigment state after a variable interval. Transmission through the rhabdomeres was measured in the eye of blowfly *Calliphora erythrocephala*. It followed that rhodopsin R490 converts into metarhodopsin M580 via two intermediates, with time constants of 700 ns and 80 μ s respectively. In the reverse pathway, i.e. the photoconversion of metarhodopsin into rhodopsin, an intermediate decaying with a time constant of 4 μ s was found. (19 refs.)

78237 A test of the dopamine hypothesis of microwave energy effects. A.H.Frey, L.S.Wesler (Randomline Inc., Huntingdon Valley, PA, USA). *J. Bioelectr. (USA)*, vol.1, no.3, p.305-12 (1982).

Exposure to low intensity microwave energy has been found to alter the behavior of test animals. Frey and Spector (URSI Annual Meeting, Amherst, USA, p.93, 1976) hypothesized that the dopamine systems of the brain may be involved in the mediation of these and other effects of the energy. The dopamine system has been implicated in the regulation of tail pressure behaviors. Thus, microwave energy exposure should modify tail pressure behaviors. This prediction was tested and it was found that microwave energy exposure does affect this set of behaviors. The pressure used as well as odor cues influences the effect. (20 refs.)

78238 Microwaves and the blood-brain barrier: a review. A.S.Segal, R.L.Magin (Dept. of Electrical Engng., Univ. of Illinois, Urbana, IL, USA). *J. Bioelectr. (USA)*, vol.1, no.3, p.351-98 (1982).

The research conducted during the past decade on the interaction of microwaves with the blood-brain barrier (BBB) is reviewed. The structure and function of the BBB is briefly described, the major results of experimental studies are summarized, and directions for future research are suggested. (42 refs.)

78239 Microwaves and neoplasia in mice: analysis of a reported risk. N.J.Roberts, Jr., S.M.Michaelson (Dept. of Medicine, Univ. of Rochester, Rochester, NY, USA).

Health Phys. (GB), vol.44, no.4, p.430-3 (April 1983). In IRE Trans. Biomed. Electron., vol.9, p.104-8, 1962, Prausnitz and Susskind reported the results of experiments designed to examine the effects of chronic exposure of mice to microwaves. They found that 'neoplasms of the white blood cells' were more prevalent in the irradiated group than in control mice, but 'longevity of the mice did not appear to be affected under the prevailing conditions'. The authors describe an analysis of Prausnitz and Susskind's experiments and discuss the original observations with regard to known effects of temperature variation on leukocyte functions. They submit that the Prausnitz and Susskind report does not support a link between exposure to microwave radiation and the development of neoplasia. (18 refs.)

78240 Experimental studies of laser thermal retinal injury. R.Birngruber, V.-P.Gabel, F.Hillenkamp (Augenklinik, Univ. Muenchen, Muenchen, Germany).

Health Phys. (GB), vol.44, no.5, p.519-31 (May 1983). In damage tests conducted on rabbit and monkey eyes, the threshold values for retinal damage resulting from different laser radiation were determined. The reproduction of the 'worst-case' situation was ensured by the test apparatus. All physical parameters, such as power/energy, exposure time, and retinal spot, were carefully controlled. Probit analysis showed a very precise determination of the threshold values based on ophthalmoscopic visibility. The attempt of a simple physical interpretation of the thresholds leads to contradictions in major points, so a detailed calculation of damage functions and thermal model calculations are necessary. (46 refs.)

Investigations on microwave radiation exposure See Entry 78356

87.50G Ionizing radiations (u.v., X-ray, gamma-ray; particle radiation effects)

78241 Mechanism of chromatin degradation in thymocytes of irradiated rats. VI. Postirradiation changes in poly (ADP-ribose)polymerase activity. N.Zotovar, S.R.Umanski, V.I.Tokarskaya (Inst. of Biological Phys., Acad. of Sci., Pushchino, USSR).

Radiobiologiya (USSR), vol.23, no.2, p.152-6 (1983). In Russian. For pt.V see *ibid.*, vol.23, no.1, p.31, 1983. A biphasic change in poly (ADP-ribose) polymerase activity of the thymocyte chromatin was observed after 10 Gy irradiation of rats: during the first minutes the incorporation of ¹⁴C-NAD increased by 40% then started decreasing to give 110, 60 and 35% after 1, 2 and 3 h, respectively. Irradiation of rat thymus chromatin in vitro sharply decreased poly (ADP-ribose) polymerase activity. The possible role of changes in the poly (ADP-ribose) synthesis in the activation of nuclear Ca/Mg-dependent endonuclease and in the postirradiation degradation of the thymocyte chromatin is discussed. (16 refs.)

78242 Cell spheroids as the object for radiobiological research. E.Kopp, G.Erntgraber, Kh.Abel' (Central Inst. of Molecular Biology, Berlin, Germany).

Radiobiologiya (USSR), vol.23, no.2, p.161-71 (1983). In Russian. Cell spheroids are conglomerates of closely arranged cells with reciprocal effects among them. Spheroids are histologically similar to nodular tumours. Cells constituting these spheroids are heterogenous in their sensitivity to X-rays and fast neutrons. The radiosensitivity of cells in a small spheroid is lower than that of similar cells grown in a monolayer. (33 refs.)

78243 Changes in the chromosome pattern of mouse lymphosarcoma cells during long-term continuous irradiation. V.Yurashkova (Inst. of Biophys., Czechoslovak Acad. of Sci., Brno, Czechoslovakia), V.Kliment, R.Tuscany, V.Drshil.

Radiobiologiya (USSR), vol.23, no.2, p.172-6 (1983). In Russian. In experiments of lymphosarcoma cells LS/BL, a study was made of changes in the chromosome pattern after long-term continuous irradiation at a low dose rate (35.8 $\times 10^{-3}$ mC.kg⁻¹.s⁻¹). To ensure reliable detection of changes in the chromosome length the method of automated computer analysis of the chromosome pattern with subsequent statistical evaluation was used. The radiation effect was manifested by a higher frequency of shape abnormalities in continuously exposed cells. (23 refs.)

78244 Comparative study of radiosensitivity of normal and regenerating tissues. I. Interphase cell death and aplasia of the regenerating and normal bone marrow and spleen of C57B1 mice. N.S.Samokhvalova, M.F.Popova (A.N. Severtsov Inst. of Evolutionary Morphology & Ecology of Animals, Acad. of Sci., Moscow, USSR).

Radiobiologiya (USSR), vol.23, no.2, p.177-81 (1983). In Russian. A comparative study of the radiosensitivity of cells of normal and regenerating tissues of bone marrow and spleen has demonstrated that a single exposure to X-rays produces a lesser damaging effect on regenerating tissues than on normal ones. The data obtained indicate that the increase in radioresistance of the organism during active regeneration of the haemopoietic organs is due not merely to the increase in the dividing cell pool of these organs but also to qualitative changes in their functional state. (15 refs.)

78245 Effects of high and superhigh doses of ⁶⁰Co- γ -quanta and fission neutrons on rats. G.A.Lavrova, L.N.Postnikov, A.G.Silina, S.N.Valter, T.V.Pushkareva, A.G.Sverdlov (B.P. Konstantinov Leningrad Inst. of Nuclear Phys., Acad. of Sci., Leningrad, USSR).

Radiobiologiya (USSR), vol.23, no.2, p.187-91 (1983). In Russian. A transient form of acute radiation sickness could be distinguished in Wistar rats after total-body exposure to ⁶⁰Co- γ -rays in high doses (150-200 Gy). With local exposure of the head, in addition to the direct damaging effect on the nervous system, the organismic factors play an important role in the development of the CNS syndrome. Effects of fractionation of superhigh doses of γ -quanta and fission neutrons were not observed. The RBE of neutrons should constitute 1.8 for the transient form of radiation sickness to develop. This value is much less than that needed for the development of haemopoietic and intestinal lesions. PAPP, 'gammaphos' and the combination of these agents do not influence the effect on rats of high doses of γ -quanta. (20 refs.)

78246 Possible influence of natural radiation background on the development of mammals. A.M.Kuzin, L.V.Slozenikina, L.A.Fialkovskaya, V.N.Primak-Mirolyubov (Inst. of Biological Phys., Acad. of Sci., Pushchino, USSR).

Radiobiologiya (USSR), vol.23, no.2, p.192-4 (1983). In Russian. The deceleration of the development of young rats during the postnatal ontogenesis under conditions of a low-background chamber (a 10-fold decrease in the natural radiation background) was detected using the criterion of individual growth of body weight for 10 days of observation. The administration, to the low-background chamber, of uranium salts, which restored the natural background (all other experimental conditions being retained) removed the effect observed. (7 refs.)

78247 Dynamics of early postirradiation changes in capillary endothelium (quantitative electron-microscopic analysis). R.P.Stepanov, V.F.Dubrovskaya. *Radiobiologiya (USSR)*, vol.23, no.2, p.196-9 (1983). In Russian.

Oedema, breakage and fragmentation of plasmalemma and mitochondrial damages developed in rats 1-48 h following total-body X-irradiation (4.5 Gy). These changes were most pronounced 2-6 h after exposure, when they spread over 20-30% of the population, and were accompanied by the appearance of wide gaps in the endothelial layer and maximal accretion of free lipids in the endotheliocyte cytoplasm. Changes in the sizes and number of mitochondria were responsible for the tendency toward the increase in their relative total volume which was most pronounced after 12 h. (15 refs.)

78248 The role of changes in the oxygen concentration upon modification of the reproductive death of cells in vitro. II. Modification of radiosensitivity with the varying rate of oxygen consumption in cells. Yu.N.Korystov (Inst. of Biological Phys., Acad. of Sci., Pushchino, USSR).

Radiobiologiya (USSR), vol.23, no.2, p.200-4 (1983). In Russian. For pt.1 see *ibid.*, vol.23, no.1, p.39, 1983. A study was made of the role of changes in the concentration of oxygen occurring upon modification of radiosensitivity of cells in vitro using temperature (0-37°C), uncoupling agents and respiration inhibitors, and also upon stimulation of the oxygen consumption by microsomes. When cells were irradiated in suspension, monolayer, spheroid and roots of plants a change in the rate of the oxygen consumption

by cells and a corresponding change in their oxygenation can contribute considerably to a radiomodifying effect. (16 refs.)

78249 Seasonal radiosensitivity of rats and dogs. S.A.Rogacheva, O.V.Luzanova, E.N.Kirillova, L.D.Murzina, T.I.Uryadnitskaya (Inst. of Biophys., USSR Ministry of Health, Moscow, USSR). *Radiobiologiya (USSR)*, vol.23, no.2, p.205-9 (1983). In Russian. Data are submitted obtained from 10.5 thousand Wistar rats and 350 mongrel dogs exposed to γ -radiation (LD_{50} - LD_{100}) in different seasons. The radiosensitivity of both animal species was highest in autumn (August and September) and lowest in winter (February and January). The seasonal DMF for rats and dogs with LD_{16} , LD_{50} and LD_{84} was 1.24 and 1.31, 1.13 and 1.17, and 1.04 and 1.07, respectively. The curves for seasonal radiosensitivity of dogs with LD_{84} , LD_{50} and LD_{16} exhibited a single-phase character throughout a year. For rats, the seasonal radiosensitivity curves with LD_{84} were single-phase, and the curve with LD_{50} , and particularly LD_{16} , exhibited the second peak of radioresistance in June. The increase in radioresistance of rats and dogs correlated with the increase in the number of leukocytes in the peripheral blood of the animals. (17 refs.)

78250 Recovery of rats from ^{252}Cf -induced damages. E.S.Zhorova, S.V.Stepanov, G.A.Zalikin (Inst. of Biophys., USSR Ministry of Health, Moscow, USSR). *Radiobiologiya (USSR)*, vol.23, no.2, p.210-15 (1983). In Russian. The types of recovery processes were demonstrated in experiments on albino rats damaged with ^{252}Cf . The frequency and the degree of manifestation of both pathological and recovery processes were functions of both the radiation dose and the time since the processes initiation. The results obtained indicate that changes induced by the incorporation of ^{252}Cf , within a wide range of doses, are compensated incompletely to be manifested later by sclerotic, hyperplastic and neoplastic processes. (8 refs.)

78251 Radiation-induced and postirradiation changes in the forest biogeocenosis after acute γ -irradiation. I. Comparison of seasonal radiosensitivity of pine-and-birch stand after acute γ -irradiation. N.N.Mishenkov, D.A.Spirin, R.M.Aleksakhin, R.T.Karaban, E.A.Fedorov, G.N.Romanov. *Radiobiologiya (USSR)*, vol.23, no.2, p.220-3 (1983). In Russian. In order to describe the state of the upper-tree layer of a pine-and-birch stand exposed at the stage of active growth (in spring) and at the resting stage (in autumn) the following parameters were determined: (a) the increase in the growth of annual shoots, (b) the loss of needles and wood biomass, (c) changes in the primary productivity, and (d) lethal doses for pine stands. According to these indices seasonal radiosensitivity of the pine stand was shown to be 2-3 times higher in spring than in autumn. (11 refs.)

78252 Destruction of gelatin irradiated in its aqueous solutions at low temperatures. N.V.Zakatova, E.O.Svanidze, V.A.Sharpatyi (Inst. of Chem. Phys., Acad. of Sci., Moscow, USSR). *Radiobiologiya (USSR)*, vol.23, no.2, p.227-30 (1983). In Russian. The methods of electrophoresis and ESR were used to determine the radiochemical yield of breaks in polypeptide chains of gelatin fractions and the formation of primary anion-macroradicals in irradiated, at 77K, 5 and 10% gelatine solutions. The obtained values gave $G(\text{breaks})=G(R_p)=0.03$. This excludes the contributions of anion-macroradicals in which free valence was localized on the fragment $-C-O^{\cdot}$ of proline and hydroxyproline residues: their isomerization leads to a change in the conformation of the macromolecule rather than to the destruction thereof. (6 refs.)

78253 Effect of α -particles on bacteriophage T4. G.A.Leont'eva, A.E.Grigor'ev, I.G.Akoev, I.M.Dmitrievskii (Inst. of Biological Phys., Acad. of Sci., Pushchino, USSR). *Radiobiologiya (USSR)*, vol.23, no.2, p.230-3 (1983). In Russian. Exponential survival curves were obtained for a dry film culture of bacteriophage T4 Br⁺ after exposure to both α -particles and γ -quanta. The relative biological effectiveness of α -particles was 4.68 with respect to survival. The mutation spectrum after α -irradiation slightly differed from that produced by γ -radiation. (3 refs.)

78254 Comparison of neutron- and γ -radiation-induced transformations of 2-deoxy-D-ribose in aqueous solutions. N.P.Krushinskaya, A.E.Serebryanyi (Inst. of Biophys., Ministry of Health, Moscow, USSR). *Radiobiologiya (USSR)*, vol.23, no.2, p.235-7 (1983). In Russian. The effectiveness of neutron radiation (1 MeV) was nearly twice as low as that of electrons and γ -quanta with regard to the formation of products of radiolysis of 2-deoxy-D-ribose in aqueous solutions. A change in the dose-rate of sparsely ionizing radiation by the order of 5-6, and variation in the concentration of 2-deoxy-D-ribose from 1 to 5 mM, did not substantially influence the G products of radiolysis. (6 refs.)

78255 Influence of dose-rate on the formation of double-strand DNA breaks. N.V.Kondakova, V.V.Sakharova (Sci. Res. Lab. of Biological Structures, Ministry of Health, Moscow, USSR). *Radiobiologiya (USSR)*, vol.23, no.2, p.243-6 (1983). In Russian. It has been shown that sparsely ionizing radiation produces double-strand DNA breaks in solution more readily at high dose-rates (20 Gy/min) than at low ones (0.03-0.06 Gy/min). Possible mechanisms of the effect observed are discussed. (14 refs.)

78256 Response of lymph and blood coagulative systems to exposure to γ -radiation at high altitudes. S.B.Daniyarov, V.V.Pukhov (Kirgiz State Medical Inst., Frunze, USSR). *Radiobiologiya (USSR)*, vol.23, no.2, p.247-50 (1983). In Russian. A study was made of coagulation and cellularity of blood and lymph of thoracic duct of dogs exposed to 2.5 Gy radiation at the altitudes of 760 m and 3200 m above sea level after one-month adaptation. Irrespective of the irradiation conditions coagulation of blood decreased and that of lymph increased. Radiation-induced changes in the cellularity of both blood and lymph were less pronounced in conditions of natural hypoxia than at the altitude of 760 m. (13 refs.)

78257 Migration of lymphocytes in conditions of internal irradiation. II. Disturbance of the microenvironment of lymphocytes in mouse organs. Yu.N.Anokhin, T.A.Norets, A.A.Yarilin (Sci. Res. Inst. of Medical Radiology, Acad. of Medical Sci., Obninsk, USSR). *Radiobiologiya (USSR)*, vol.23, no.2, p.256-9 (1983). In Russian. At later times after the injection of selenium-75-selenium methionine to CBA mice a long lasting inhibition of migration of intravenously injected normal ^{51}Cr lymphocytes to the lymph nodes and liver was found. On the contrary, no changes in the normal lymphocyte migration within the animal body were observed after total-body γ -irradiation with a dose of 4 Gy. The data obtained are indicative of a radiation-induced disturbance of the microenvironment factors, which affect migration of lymphocytes within the body, during the long-term exposure to radiation emitted by the incorporated source. (13 refs.)

78258 Regularities of postirradiation recovery of the organism in conditions of external nonuniform irradiation. VII. Postirradiation radiosensitivity of rats as function of the preirradiation dose with an oral form of radiation sickness. G.M.Avetisov, R.N.Zaitseva, M.V.Sergeeva (Inst. of Biophys., USSR Ministry of Health, Moscow, USSR). *Radiobiologiya (USSR)*, vol.23, no.2, p.263-7 (1983). In Russian. Radiosensitivity of rats was studied after double X-irradiation of the head, first with doses of 15 and 13 Gy, then with 8-21 Gy. (8 refs.)

78259 Changes in the electric activity of rat stomach directly affected by X-radiation. K.P.Balitskii, A.V.Syromyatnikov, L.P.Voitenko (R.E. Kavetsky Inst. of Oncology Problems, Acad. of Sci., Kiev, Ukrainian SSR). *Radiobiologiya (USSR)*, vol.23, no.2, p.267-71 (1983). In Russian. In experiments on rats inhibition of the electric activity of X-irradiated stomach was discovered. The disturbance of the nervous regulation of the exposed stomach was manifested mainly by inhibition of the transmission of exciting stimuli via choline- and serotonin-reactive structures of the vegetative nervous system. The administration of serotonin and phentolamine normalized the stomach activity. (16 refs.)

78260 Affection of dogs estimated by some integral indices after the combined effect of external γ -irradiation and inhalation of ^{239}Pu submicron dioxide. Z.I.Kalmykova, A.P.Nifatov (Inst. of Biophys., USSR Ministry of Health, Moscow, USSR). *Radiobiologiya (USSR)*, vol.23, no.2, p.271-4 (1983). In Russian. The possibility of quantitation of the organism affection by the combined effect of external γ -irradiation (103.2 and 51.6 mC/kg) and succeeding inhalation of different amounts of ^{239}Pu submicron dioxide was shown on 55 mongrel dogs using the following criteria: the rate of extracellular fluid accretion and the body weight loss. (14 refs.)

78261 Combined effect of ^{239}Pu and external γ -radiation on pregnant and lactating rats. E.P.Ovcharenko, T.P.Fomina (Inst. of Biophys., Ministry of Health, Moscow, USSR). *Radiobiologiya (USSR)*, vol.23, no.2, p.275-7 (1983). In Russian. Exposure of pregnant and lactating rats to external γ -radiation (12.9-103.2 mC/kg) caused ^{239}Pu redistribution within their bodies. The increase in the transfer of ^{239}Pu to the progeny was maximum after γ -irradiation of pregnant rats with a dose of 25.8 mC/kg. The decrease in the intake of ^{239}Pu by the progeny was maximum after γ -irradiation of lactating rats with a dose of 12.9 mC/kg. Comparing the combined effect of γ - and α -radiation, γ -radiation was shown to play the major role in the embryos death. (7 refs.)

78262 The induction of chromosome aberrations in human lymphocytes by exposure to tritiated water in vitro. J.S.Prosser, D.C.Lloyd, A.A.Edwards, J.W.Stather (Nat. Radiological Protection Board, Didcot, England). *Radiat. Prot. Dosim. (GB)*, vol.4, no.1, p.21-6 (1983). An in vitro dose response has been obtained from chromosome aberration induction in human lymphocytes exposed for 24 hours to tritiated water in whole blood. An RBE at low doses of 1.13 ± 0.18 has been calculated by comparison with 250 kVp X-rays. The application of these results in cases of accidental exposure to tritiated water is discussed. (24 refs.)

78263 Studies into certain specificities of gamma-ray mutants and the parent strain *Humicola lutea* 72, producing acid protease. P.P.Aleksieva, A.A.Djerova, I.V.Grigorov, P.D.Sheremetska (Inst. of Microbiology, Bulgarian Acad. of Sci., Sofia, Bulgaria). *C.R. Acad. Bulg. Sci. (Bulgaria)*, vol.36, no.3, p.361-64 (1983). Gamma-ray exposure can be used as a mutagenic factor for obtaining mutants from a fungi strain of *Humicola lutea* 72, producing acid protease. The aim of the authors' work was to undertake a comparative morphological and physiological study of the most active mutants and the parent strain. (8 refs.)

78264 Life-table factors for use in estimating the cancer risk of radiation exposure to workers. H.D.Maillie (Dept. of Radiation Biology & Biophys., Univ. of Rochester School of Medicine & Dentistry, Rochester, NY, USA). *Health Phys. (GB)*, vol.44, no.4, p.317-27 (April 1983). Recent publications have discussed the use of life-tables in estimating the risks of radiation-induced cancer (B. Bunker et al., *ibid.*, vol.40, p.439, 1981; N.H. Harley and B.S. Pasternack, *ibid.*, vol.40, p.307, 1981). These studies have been useful in estimating the hazards to groups of individuals exposed to radiation. However, they are not always presented in a way which is useful to health physicists. Life-table factors are presented here which may be of use in calculating such risks to individuals or groups. (12 refs.)

78265 Problems with the linear-quadratic dose-response relationship. P.R.J.Burch (Dept. of Medical Phys., Univ. of Leeds, Leeds, England). *Health Phys. (GB)*, vol.44, no.4, p.411-13 (April 1983). The BEIR-III Report (*ibid.*, vol.41, p.769-74, 1981) assumes that the total risk (R) of cancer, after an absorbed dose D of low-LET radiation, is given by: $R = \alpha_0 + \alpha_1 D + \alpha_2 D^2$, where α_0 is the risk in the absence of radiation exposure and the constants α_1 and α_2 , valid over a limited dose range, are derived from observations on irradiated populations. The author feels that although this equation may sometimes offer an acceptable approximation to dose-response relations at low D, the values of α_1 and α_2 will usually have to be derived from observations at relatively high D where it will seldom be legitimate to ignore the complications outlined here, particularly those relating to repair mechanisms. (9 refs.)

78266 Induction and repair of DNA strand breaks in CHO-cells irradiated in various phases of the cycle. S.Graubmann, E.Dikomey (Inst. of Biophys. & Radiobiology, Univ. of Hamburg, Hamburg, Germany). *Int. J. Radiat. Biol. (GB)*, vol.43, no.5, p.475-83 (May 1983). Induction and repair of DNA strand breaks was investigated in synchronized CHO cells by using the alkaline DNA-unwinding technique followed by chromatography on hydroxyapatite. The velocity of DNA denaturation in an alkaline solution (pH 12.1) was found to be independent of the position in the cycle. In unirradiated cells the number of DNA strand breaks per 3.6×10^{12} dalton was found to vary with age in cell cycle amounting to about 250 breaks per cell for G₁, 400 for S, and 500 for G₂+M cells. The number of induced DNA strand breaks per unit dose was found to be the same in all phases; an average of 340 strand breaks were induced per Gy and per 3.6×10^{12} dalton. Within the first hour after irradiation about 90 per cent of all radiation-induced strand breaks are rejoined. (27 refs.)

78267 Radiation sensitivity of DNA-metal complexes: a pulse radiolysis study. P.C.Beaumont, E.L.Powers (Patterson Labs., Univ. of Texas, Austin, TX, USA). *Int. J. Radiat. Biol. (GB)*, vol.43, no.5, p.485-94 (May 1983). The effect of silver(I) and mercury(II) complexing upon the rate of reaction of both the hydrated electron and the OH radical with DNA has been investigated using the technique of pulse radiolysis. The results presented do not support the hypothesis that the mechanism of radiation sensitivity by these metals is mediated through increased rate of free radical attack upon DNA. Also, there is evidence presented that neither metal, when complexed with DNA, reacts at a significant rate with the free radical species e_{aq}^{\cdot} and OH.

The technique of pulse radiolysis was also used to study the complexation of both silver(I) and mercury(II) with DNA (calf-thymus, 40 per cent GC). Scatchard plots, derived from the experimental data, gave association constants of $1.85 \times 10^5 \text{ dm}^3 \text{ mol}^{-1}$ and $9.9 \times 10^4 \text{ dm}^3 \text{ mol}^{-1}$ and n values (number of complexing sites per nucleotide) of 0.71 and 0.31 for silver(I) and mercury(II) respectively. (27 refs.)

78268 Immuno-electrophoretic study of the effect of radiation on protein mixtures. J.Maffei, M.Soszynski, T.C.Bog-Hansen (Protein Lab., Univ. of Copenhagen, Copenhagen, Denmark). *Int. J. Radiat. Biol. (GB)*, vol.43, no.5, p.541-50 (May 1983). Demonstrates the suitability of immuno-electrophoretic methods in studies of radiation effects on protein mixtures. Single serum proteins (IgG, albumin, transferrin), albumin-transferrin mixtures and human serum were irradiated with doses of 3-52 kGy. The irradiated proteins were analysed using rocket-, crossed-, crossed-with-intermediate-gel, and fused-rocket immuno-electrophoretic methods. Using crossed immuno-electrophoresis with intermediate gel, complex formation between albumin and transferrin was observed. Gel filtration monitored by fused-rocket immuno-electrophoresis was demonstrated to be a most promising method for studying protein degradation and hybrid formation. (15 refs.)

78269 Kinetics of double strand break repair in the DNA of X-irradiated synchronized mammalian cells. D.Blocher, M.Nusse, P.Bryant (GSF-Abteilung für Biophys. Strahlenforschung, Frankfurt am Main, Germany). *Int. J. Radiat. Biol. (GB)*, vol.43, no.5, p.579-84 (May 1983). Reports on experiments in which the kinetics of repair of DNA double strand breaks (DSB) in Ehrlich ascites tumour cells was measured in G1-, G1/S-, late S- and G2-phases. Measurements have been made using both the neutral sucrose gradient centrifugation, and the unwinding method (Bryant and Blocher 1980). It is concluded that the repair of DSB in the DNA of X-irradiated cells proceeds at approximately the same rate in all the major phases of the cell cycle, and that the cell cycle dependent variation in radiosensitivity observed in mammalian cells cannot be attributed to deficiencies in the ability of cells to repair DSB at certain cycle stages. (24 refs.)

78270 How to assess natural risks. M.Sakka (Tohoku Radiological Sci. Center, Sendai-shi, Japan). *J. Radiat. Res. (Japan)*, vol.23, no.4, p.411-22 (Dec. 1982). [received: May 1983] The low dose considered here is about 2R in 40 years which corresponds to the difference in the highest and the lowest background radiations in several prefectures in Japan. Examples of risk are cancer of adults (40-79 years old) and of childhood (0-9 years old) and childhood vital statistics. The quantity of risk is expressed in 10^{-5} Y^{-1} for cancers and in 10^{-3} Y^{-1} for childhood vital statistics with a standard deviation which gives the estimates uncertainty. Risk factors of the ICRP are given in terms of $10^{-2} \sim 10^{-5} \text{ Sv}^{-1}$. The risk factors provide convenient measures for point assessment of lifetime detriment after the relevant population is expired. But the risk factor is not satisfactory for public health purposes because it does not give annual rate nor statistical variation of the total detriment. The purpose of this report is to supplement some insufficiency of risk estimation. (9 refs.)

78271 Comparison of type and frequency of chromosome aberrations by conventional and G-staining methods in Hiroshima atomic bomb survivors. K.Ohtaki (Dept. of Clinical Labs., Radiation Effects Res. Found., Hiroshima, Japan), H.Shimba, A.A.Awa, T.Sofuni. *J. Radiat. Res. (Japan)*, vol.23, no.4, p.441-9 (Dec. 1982). [received: May 1983]

Somatic chromosomes derived from lymphocytes of 23 Hiroshima A-bomb survivors were analyzed to determine the type and frequency of radiation-induced chromosome aberrations, using both the ordinary staining method (O-method) and the trypsin G-banding method (G-method). Of 896 cells examined, 342 had aberrations, including 31 unidentifiable cells even by the G-method. The number of aberrations detected was 376 in 31P-cells. The majority of them were intra- or inter-chromosomal symmetric exchanges, while only 24 were found to be asymmetric exchanges (dicentric, rings and interstitial deletions). Further, 28 aberrations included acentric fragments and terminal deletions, and the remaining 36 were complex intra- and inter-chromosomal exchanges showing insertions and double translocations. An analysis of the same metaphases examined by sequential O- and G-methods was carried out independently on 361 aberrations. It was found that 78 were detectable only by the G-method; among these were 14 paracentric inversions, 48 reciprocal interchanges of chromosome segments with either equal or unequal length, 14 minor deletions and 2 complex rearrangements, all of which were judged as the normal variation by the O-method. In contrast, 25 aberrations detected by the O-method were found to show normal banding patterns by the G-method. (12 refs.)

78272 Changes in radiosensitivity of the in vitro fertilized mouse ova during zygotic stage from fertilization to first cleavage. T.Yamada, O.Yukawa, Y.Matsuda, A.Ohkawa (Div. of Biology, Nat. Inst. of Radiological Sci., Chiba, Japan). *J. Radiat. Res. (Japan)*, vol.23, no.4, p.450-6 (Dec. 1982). [received: May 1983]

The radio sensitivity of mouse zygotes fertilized in vitro (BC3F₁ ovum × ICR sperm) to X-rays has been measured as a function of time from fertilization to first cleavage. The dose of X-rays (LD₅₀) required to prevent development of 50% of the zygotes to the blastocyst stage in vitro varied markedly depending on the time of irradiation from about 40 to 400 R. Sensitivity is relatively low shortly after sperm entry and becomes extremely high (LD₅₀, 40 R) at the stage just before pronuclear formation (4 to 6 hr after insemination). In the later pronuclear stage (12 hr of fertilization) the sensitivity becomes low (LD₅₀, about 400 R), and it increases again just before first cleavage. (12 refs.)

78273 Modeling three-dimensional computer reconstructions from surface contours for diagnostic imaging. L.T.Cook, P.N.Cook, S.J.Dwyer, S.Batnitsky, Kyo Rak Lee, H.I.Price (Dept. of Diagnostic Radiology, Univ. of Kansas Coll. of Health Sci., Kansas City, KS, USA). *Proc. SPIE Int. Soc. Opt. Eng. (USA)*, vol.359, p.152-5 (1983). (Applications of Digital Image Processing IV, San Diego, CA, USA, 24-27 Aug. 1982). Digital medical imaging modalities construct and display images as cross-sections of anatomy. The technologies of these digital systems are moving towards thinner cross-section thicknesses, higher spatial resolutions, and larger dynamic ranges. These imaging modalities provide cross-sectional displays in which there is no superimposing of organs. This provides relatively precise two-dimensional geometric information. Information regarding the general three-dimensional (3-D) space relationships among a number of anatomic structures is difficult to acquire from a large number of thin serial sections. Clinicians are required to visualize such information by mentally stacking these serial sections to obtain the complete structure. A number of 3-D surface reconstruction algorithms have been developed for displaying 3-D anatomic structures on raster graphic displays. The authors present a comparison among these reconstruction algorithms for: (1) computation time; (2) algorithm complexity; (3) computer storage requirements; and (4) clinical efficacy. The authors will report on a three-year study of the clinical utilization of 3-D display algorithms using raster graphic display systems. (19 refs.)

78274 Physical constraints in the optimization of medical imaging filters for maximum signal-to-noise ratio. P.R.Moran (Depts. of Radiology, Phys. & Medical Phys., Univ. of Wisconsin, Madison, WI, USA). *IEEE Trans. Med. Imaging (USA)*, vol.MI-1, no.3, p.197-204 (Nov. 1982). [received: May 1983]

To filter an image by an aperture function $A(r)$, or in Fourier space by it transform $A(f)$, requires that $A(r)$ and $A(f)$ are physically realizable and mathematically exist as transform pairs. This constrains both functions to being square-integrable to guarantee their uniform convergence both in spatial and frequency domains. This paper presents a general method for deriving filter forms which maximize image SNR and also satisfy the existence constraints. The author shows that asymptotic limiting forms of the constrained filters reduce to the 'ideal observer' result, but demonstrates that the 'ideal' filter form has a divergent square integral in some simple cases important in medical imaging. The author applies these properly constrained filter forms to radiographic image and CT image models, and derives the range of arguable signal-to-noise advantage, which 'more' optimum filters may exhibit with respect to the simple 'matched' filter limit. (7 refs.)

87.60B Sonic and ultrasonic radiation

78275 Biological signals processing: an application to ultrasonic echo signals sounding. P.Larizza, B.Castagnolo (Univ. di Bari, Bari, Italy). *Electron. Oggi (Italy)*, no.3, p.97-106 (March 1983). In Italian. Ultrasonic echo signals processing in medical diagnostics and biological research is discussed. Relevant computer programs are reviewed including selected hardware. Signal filtering methods are detailed analysing inverse filtering, LMS, LMSA, FFT CLS and homomorphic filtering techniques. Computer processing methods are compared with a conclusion that FFT (Fast Fourier Transforms) algorithms are most expedient. (4 refs.) T.H.

78276 Velocity detection of Korotkoff sounds. A.E.Sibley, T.Winsor, D.A.Grigsby, E.Pischel. *Med. Instrum. (USA)*, vol.17, no.2, p.159-62 (March-April 1983). High-speed oscillograms were made showing the time relationships between the ECG and arterial pressure waves detected by three microphones successively placed beneath a standard blood pressure cuff along the brachial artery. As the cuff was deflated through the systolic/diastolic range, the indicated propagation velocity of the Korotkoff waves changed from approximately 1 m/sec near systolic pressure to about 2.5 m/sec near diastolic pressure. Non-Korotkoff waves (noise artifacts), on the other hand, were observed to propagate at much higher velocities, on the order of 5-10 m/sec. This phenomenon can be utilized to identify Korotkoff waves in the presence of other disturbances, particularly in exercise situations, and to determine diastolic pressure in the presence of arterially conducted valve and turbulence noise. (24 refs.)

78277 Feasibility of ultrasound hyperthermia in the treatment of malignant brain tumors. R.H.Britt, B.E.Lyons, D.W.Pounds, S.D.Pronas. *Med. Instrum. (USA)*, vol.17, no.2, p.172-7 (March-April 1983). In order to test the biological feasibility of using ultrasound-generated hyperthermia for the treatment of brain tumors, damage threshold studies and thermal dosimetry studies as a function of temperature were performed in 44 acute experiments in cats. Bilateral craniotomies were performed to expose the dural surface. Ultrasonic radiation was applied for 50 minutes at different intensities to generate temperatures up to 48°C. Thermal fields were mapped using an electrode array to three triple-junction thermocouple probes. The results of this study are important in two respects. First, it demonstrates that ultrasound can effectively heat the brain in an extremely controlled and precise manner. Second, the brain can withstand temperatures to 42°C without showing histological evidence of damage, which is the temperature range at which neoplastic cells begin to show cytotoxic effects. (35 refs.)

78278 Algorithms and experimental results in acoustic tomography using Rytov's approximation. M.Soumekh, M.Kaveh, R.K.Mueller (Dept. of Electrical Engng., Univ. of Minnesota, Minneapolis, MN, USA). Proceedings of ICASSP 83, IEEE International Conference on Acoustics, Speech and Signal Processing, Boston, MA, USA, 14-16 April 1983 (New York, USA: IEEE 1983), p.135-8 vol.1. Theoretical, algorithmic and experimental results on the use of Rytov's approximation in acoustic tomography are presented. The approximation error is related to the disturbance size and magnitude. A method of phase unwrapping which is based on a combination of profile to profile phase comparison coupled with some well-known phase unwrapping algorithms used in signal processing is introduced. Frequency and spatial domain reconstructions are compared with respect to computational efficiency and accuracy of interpolation. (6 refs.)

87.60D Electric and magnetic fields (d.c. and pulsed)

- 78279** A symmetric third order gradiometer without external balancing for magnetocardiography. A.C.Bruno, P.Costa Ribeiro (Dept. de Fisica, Pontificia Univ. Catolica de Rio de Janeiro, Rio de Janeiro, Brazil). *Cryogenics (GB)*, vol.23, no.6, p.324-6 (June 1983).
A feasibility study is being carried out on the operation of a SQUID gradiometer without any balancing techniques in a non-shielded environment. The paper compares empirically the performances of second and third order gradiometers; it also presents a general procedure for the design of third order gradiometers, taking into account the measured spatial dependence of the magnetic field of the human heart. The performance of a third order gradiometer is very promising for a noisy environment; it has a better low frequency noise rejection than the second order gradiometers tested, and needs no external balancing. (10 refs.)
- 78280** Neuromagnetic measurements at hospital: instrumentation and preliminary tests. P.Nicolas (INSERM, Paris, France), D.Duret, D.Teszner, T.Tuomisto. *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.184-94 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).
A SQUID system was specially built in a Parisian hospital, allowing neuromagnetic measurements in clinical investigations. A second-order symmetrical gradiometer operates inside an eddy current shield. This was designed for optimising the cost and the efficiency of the system. Its performances were tested with data from patients and normal subjects. (13 refs.)
- 78281** High-resolution magnetic measurements of human cardiac electrophysiological events. R.R.Fenici (Unita di Biomagnetismo Cardiovascolare, Univ. Cattolica, Roma, Italy), G.L.Romani, S.N.Erne. *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.231-47 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).
The fundamental motivation for investigating cardiac electrophysiological phenomena by means of the biomagnetic method has been that this technique should have added spatial resolution and provided complementary information as opposed to electric recordings only. So far the interest of experimentalists has been concentrated on two different kinds of cardiac phenomena: (1) the study of the activity of the cardiac conduction system and (2) of abnormally delayed ventricular depolarisation (late potentials). The clinical interest for the noninvasive investigation of the His-Purkinje system is well known. Noninvasive clinical recording of late potentials is particularly desirable as they seem to be precious markers for risk of sudden death. A review of the state of research in both fields is presented. (37 refs.)
- 78282** High-resolution recordings of the PR segment in magnetocardiography. S.N.Erne, R.R.Fenici, H.D.Hahlbohm, M.Masselli, H.P.Lehmann, Z.Trontelj (Phys.-Tech. Bundesanstalt, Inst. Berlin, Berlin, Germany). *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.248-54 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).
The PR interval of magnetocardiograms has been measured with a SQUID sensor in the Berlin magnetically shielded room. In addition to previously reported ramps with isolated superimposed signals in several cases a structured morphology has been found. (8 refs.)
- 78283** High-resolution isofield mapping ion magnetocardiography. S.N.Erne, R.R.Fenici, H.D.Hahlbohm, W.Jaszczuk, H.P.Lehmann, M.Masselli (Phys.-Tech. Bundesanstalt, Inst. Berlin, Berlin, Germany). *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.291-300 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).
A possible clinical application of a high-resolution magnetic isofield contour mapping technique in cardiography is discussed. Preliminary results are presented in applying this technique to patients with recent myocardial infarction. The patients could be divided into two classes; one of them contained patients with late electrical potentials as a subclass. (9 refs.)
- 78284** Comparison between measured and simulated magnetocardiograms in a case of anterolateral myocardial infarction. P.Siltanen (Cardiovascular Lab., Helsinki Univ. Central Hospital, Helsinki, Finland), T.Poutanen, T.Katila, M.Seppanen, T.Varpula. *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.301-10 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).
The MCGs measured in a case of an anterolateral myocardial infarction were compared with the corresponding simulated MCGs. The most distinctive changes in the measured MCGs were observed in the upper and lower parts of the thorax as predicted by the simulation. (13 refs.)
- 78285** High-resolution magnetocardiographic recordings of the ST segment in patients with electrical late potentials. S.N.Erne, R.R.Fenici, H.D.Hahlbohm, W.Jaszczuk, H.P.Lehmann, M.Masselli (Phys.-Tech. Bundesanstalt, Inst. Berlin, Berlin, Germany). *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.340-5 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).
High-resolution magnetocardiograms of patients with recent myocardial infarction have been recorded. In three cases, signals have been found in the ST segment that are time correlated with simultaneously recorded late electric potentials. (5 refs.)
- 78286** Optimizing vector magnetocardiographic lead fields by using a physical torso model. H.Eskola, J.Malmivuo (Electronics Lab., Tampere Univ. of Technol., Tampere, Finland). *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.356-67 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).
The ideality and sensitivity of several vector magnetocardiographic leads were tested by using an inhomogeneous, physical torso model. The postero-anterior component of the heart's magnetic vector was found easiest to detect. New, more ideal leads for the other two components are suggested. However, these have lower sensitivity. The differences from the results of former investigators can be explained by the differences of the models. (13 refs.)

87.60G Laser beams, microwaves, and other electromagnetic waves

(inc. NMR; for X-rays and gamma-rays, see 87.60J)

- 78287** A lamp for cancer phototherapy. F.Jacka (Mawson Inst. for Antarctic Res., Univ. of Adelaide, Adelaide, Australia), A.J.Blake. *Aust. J. Phys. (Australia)*, vol.36, no.2, p.221-6 (1983).
A lamp described comprises a 1000 W incandescent filament source, long- and short-wave pass filters, and a non-imaging reflector system. The output of 24 W in the 620-720 nm band is delivered through a 53 mm diameter aperture with a maximum divergence half-angle of 60°. Refracting components may be fitted to modify the output angular or intensity distribution. This lamp has been used to irradiate several different types of malignant tumour in human patients, following intravenous injection of the photoactive drug haematoporphyrin derivative, causing selective necrosis of the malignant tissue. The clinical results are regarded as encouraging. (7 refs.)
- 78288** Three-dimensional display of nuclear magnetic resonance (NMR) cardiovascular images. L.Axel, G.T.Herman, J.K.Udupa (Dept. of Radiology, Univ. of Pennsylvania, Philadelphia, PA, USA), P.A.Bottomley, W.A.Edelstein. *J. Comput. Assisted Tomogr. (USA)*, vol.7, no.1, p.172-4 (Feb. 1983).
A set of contiguous nuclear magnetic resonance images of the thorax of a living dog was used to create various types of three-dimensional display of the myocardium and great vessels. These structures can be displayed separately or together as transparent or opaque surfaces and can be shown as rotating three-dimensional figures. (11 refs.)
- 78289** Medical laser equipment for continuous operation. G.F.Fedotkin, G.A.Skorubskii (All-Union Sci. Res. Inst. of Medical Instrument Manufacture, Moscow, USSR). *Biomed. Eng. (USA)*, vol.16, no.4, p.133-6 (July-Aug. 1982). Translation of: *Med. Tekh. (USSR)*, vol.16, no.4, p.39-43 (July-Aug. 1982). [received: April 1983]
When designing medical laser equipment special attention is paid to the development of the systems for transmitting radiation to the irradiated object, to visual guidance systems for the infrared radiation, and to systems for controlling the exposure dosage and density of the laser radiation. The authors consider basic diagrams that provide solutions for these problems when using laser radiation in surgery and therapy. (9 refs.)
- 78290** Technique and method of bronchography. R.M.Mamlyayev, I.P.Nalimov, V.M.Antonov, A.Kh.Shakirov (N.A.Semashko Moscow Medical Stomatologic Inst., Moscow, USSR). *Biomed. Eng. (USA)*, vol.16, no.4, p.137-8 (July-Aug. 1982). Translation of: *Med. Tekh. (USSR)*, vol.16, no.4, p.43-5 (July-Aug. 1982). [received: April 1983]
Preliminary data suggest that bronchography creates new prospects for investigation of the bronchi under normal and pathological conditions, enables the depth of the bronchi, their mutual arrangement, and location of the blood vessels to be determined, and the direction, course and angles of branching of the bronchi to be established. (2 refs.)
- 78291** Cardio-surgical thermography. A.R.Fiorini, R.Fumero, R.Marchesi (Dipartimento di Energetica, Politecnico di Milano, Milano, Italy). *Proc. SPIE Int. Soc. Opt. Eng. (USA)*, vol.359, p.249-56 (1983). (Applications of Digital Image Processing IV, San Diego, CA, USA, 24-27 Aug. 1982).
Extracorporeal circulation allows direct access inside the chest: it may be used to carry out physiological research. The thermo-chemical protection of myocardium during heart surgery, called cardioplexy, is one of the latest outstanding techniques in patient safety. Thermocardiography monitoring during the infusion of the cardioplegic solution allows continuous assessment of rapid temperature distribution changes and shows exactly the extent of myocardium involved. Using a peculiar pseudocolor digital image enhancement, it is possible to emphasize involved areas coronary flow and to model the thermofluid-dynamical actions of inspected heart. (5 refs.)
- 78292** Study of RF, gradient pulse and magnet instability effect in NMR tomography. C.H.Oh, H.S.Kim, H.W.Park, W.S.Kim, S.W.Lee, Z.H.Cho (Korea Advanced Inst. of Sci., Seoul, Korea). *IEEE Trans. Nucl. Sci. (USA)*, vol.30, no.3, p.1899-904 (June 1983).
Newly emerged NMR imaging requires careful studies of RF pulse shapes and sequencing for the selection of the region, gradient pulsing for the 2- or 3-D spatial coding, and suitable signal handling technique for the compensation of the inherent instability of the system, especially fluctuation of the static magnetic field. The above subjects are discussed in detail and a new method for the line integral projection reconstruction is proposed. The method could equally be applied to other 3-D NMR imaging techniques such as KWE (Kumar-Welt-Ernst) direct Fourier reconstruction or planar integral projection type reconstruction. (10 refs.)
- 78293** Infrared radiation in therapeutic hyperthermia. J.Dutreix (Faculte de Medecine, Alexandrie, Egypt), E.Damia, A.Salama, P.Janoray, J.-M.Cosset. *J. Biophys. & Med. Nucl. (France)*, vol.7, no.1, p.25-35 (1983). In French.
Infrared radiation provides a convenient way for heating superficial tumours. Geometrical and spectral distributions have been studied for a commercial radiator (Philips). The attenuation of the radiation has been measured in phantom and biological media with a diode. The thermal distribution has been studied with thermocouple in phantoms and in living tissues. The temperature distribution has been theoretically computed as a function of the applied radiation intensity and superficial cooling by air blowing. Measurements and computations show that reasonably uniform heating can be achieved throughout a thickness approaching 1 cm. Therapeutic results for 25 patients are reported. (13 refs.)
- 87.60J Corpuscular radiation and radioisotopes**
(inc. X-rays and gamma-rays)
- 78294** Superimposition of krypton-81 m single photon emission CT and X-ray CT images for cerebral blood flow evaluation. T.Higa, S.Tanada, W.Taki, H.Fukuyama, Y.Ishii, T.Fujita, Y.Yonekawa, T.Odori, T.Mukai, H.Handa, M.Kameyama, R.Morita, K.Torizuka (Kyoto Univ. Hospital, Kyoto, Japan). *J. Comput. Assisted Tomogr. (USA)*, vol.7, no.1, p.37-41 (Feb. 1983).
Selective arteriographic infusion of krypton-81 m was used to obtain cerebral single photon emission computed tomograms. These were then superimposed on X-ray computed tomograms to assess topographically the perfusion of the entire brain. This method enhances the detecting capability for abnormal perfusion areas and has been used in 21 patients with various brain diseases. (7 refs.)

- 78295 Correction for scattered radiation in a ring detector positron camera by integral transformation of the projections.** M.Bergstrom (Dept. of Neuro-radiology, Karolinska Hospital, Stockholm, Sweden), L.Eriksson, C.Bohm, G.Blomqvist, J.Litton.
J. Comput. Assisted Tomogr. (USA), vol.7, no.1, p.42-50 (Feb. 1983).
A 'deconvolution' algorithm for the determination of the scatter contribution in positron emission tomography is described. The projected distributions of scattered radiation measured with a line source at different positions in water phantoms are described analytically. It is shown that an integral transformation of the observed projections with a slightly modified analytical function gives an adequate description of the scattered radiation. The scatter distribution from any composite object can thus be calculated and subsequently subtracted. The algorithm is tested on different objects. The result shows that the level of scattered radiation can be reduced from 25 to 1% of the total count rate in the center of the projection from a homogeneous phantom. (19 refs.)
- 78296 Element-sensitive computed tomography with fast neutrons.** J.C.Overly (Dept. of Phys., Univ. of Oregon, Eugene, OR, USA).
J. Comput. Assisted Tomogr. (USA), vol.7, no.1, p.117-25 (Feb. 1983).
Neutrons and X-rays are mathematically equivalent as probes in computed tomography. However, structure in the energy dependence of neutron total cross sections and the feasibility of using time-of-flight techniques for energy sensitivity in neutron detection suggest that spatial distributions of specific substances can be determined from neutron transmission data. It is demonstrated that this is possible by tomographically reconstructing from such data a phantom containing several different structural materials. (10 refs.)
- 78297 Organ and lesion volume measurements with computed tomography.** M.H.Reid (Dept. of Radiology, Univ. of California Davis Medical Center, Sacramento, CA, USA).
J. Comput. Assisted Tomogr. (USA), vol.7, no.2, p.268-73 (April 1983).
Useful clinical information will often result from determinations of organ and lesion tissue volumes from measurements of computed tomographic (CT) cross sections. This paper discusses simple applications of stereology to volume estimations of organs and disease processes. The method is applied to CT sections and, for equivalent accuracy, is less time consuming than planimeter or CT scanner region of interest outlining and measurements. (7 refs.)
- 78298 A Monte Carlo simulation of Compton scattering in positron emission tomography.** J.Logan, H.J.Bernstein (Dept. of Chem., Brookhaven Nat. Lab., Upton, NY, USA).
J. Comput. Assisted Tomogr. (USA), vol.7, no.2, p.316-20 (April 1983).
A Monte Carlo technique was used to simulate some of the important physical processes involved in the coincidence detection of gamma rays by a positron emission tomograph. The major effect considered here is the detection of Compton scattered gamma rays as coincidence counts. The Compton scattering of gamma rays in a H_2O filled phantom was simulated using the Klein-Nishina cross section. Results obtained in the form of profiles of activity were compared to a model which represents scatter as the convolution of the true signal with an exponential. (12 refs.)
- 78299 Computer technique for monitoring time dependent changes from sequential CT images.** R.F.Mattrey, S.A.Long (Dept. of Radiology, Univ. of California, San Diego, CA, USA), S.W.Erickson, C.B.Higgins.
J. Comput. Assisted Tomogr. (USA), vol.7, no.2, p.379-82 (April 1983).
The sequential computed tomography (CT) images used in this manuscript are electrocardiogram-gated images of the same cross section of the heart (10 in this study) depicting one cardiac cycle from end-diastole to the next end-diastole. Each of these 10 reconstructions corresponds to 10% intervals extending from one R wave to the next R wave. When each image of the series of 10 images is assigned a consecutive table position, using the program for sagittal reconstructions a chronogram along any line through the X-Y plane of the left ventricular (LV) wall can be produced. The chronograms display changes in wall thickness and wall motion in relation to time throughout the cardiac cycle at a preselected site in the LV and can be used to demonstrate the LV myocardial response to perturbations. This technique adds the dimension of time to spatial information in the CT images and can be used to monitor cardiac physiology in a quantitative fashion. (5 refs.)
- 78300 Development prospects for power supplies for diagnostic X-ray sets.** V.V.Klyuev, G.I.Dmitriev, V.P.Kurozav, V.A.Bakushev, L.V.Vladimirov, N.P.Kolesnikov, K.A.Pimenov, P.G.Smetanin, V.Yu.Khlebtsevich, A.Z.Shvartsman (Spektr Production Cooperative, Moscow, USSR).
Biomed. Eng. (USA), vol.16, no.4, p.99-104 (July-Aug. 1982). Translation of: *Med. Tekh. (USSR)*, vol.16, no.4, p.3-9 (July-Aug. 1982). [received: April 1983] (6 refs.)
- 78301 Basic quality parameters of X-ray diagnostic equipments.** A.M.Gurvich, N.N.Blinov (Moscow X-Radiological Res. Inst., Min. of Health, Moscow, USSR).
Biomed. Eng. (USA), vol.16, no.4, p.105-11 (July-Aug. 1982). Translation of: *Med. Tekh. (USSR)*, vol.16, no.4, p.10-18 (July-Aug. 1982). [received: April 1983]
The quality parameters of X-ray diagnostic facilities (X-ray sets, tubes, and detectors) play an important part in obtaining the maximum diagnostic information with a minimum radiation exposure, since they control the optimum conditions for obtaining an X-ray picture. Recent advances in research on the factors controlling image quality go with advances in image intensification and transformation to make it necessary to reconsider the parameters of X-ray diagnostic systems. The present authors consider mainly what needs to be measured and standardized, not how to do it. (19 refs.)
- 78302 Effects of X-ray hardness on fluorogram informativeness.** G.A.Chuiko, V.M.Tsvetkov (Flaw-Detection Res. Inst., Moscow, USSR).
Biomed. Eng. (USA), vol.16, no.4, p.117-19 (July-Aug. 1982). Translation of: *Med. Tekh. (USSR)*, vol.16, no.4, p.23-6 (July-Aug. 1982). [received: April 1983]
It is possible to replace X-radiography by fluorography using image intensifiers II only if the two methods are equivalent in informativeness. The informativeness of a fluorogram is dependent not only on the constraints arising from the method and from the parameters of the II but also on the working conditions, which are related to the mode of operation of the power supply. As an example, the authors consider a fluorograph that includes the URPF power supply, which employs a single-phase source with a full-wave rectification circuit. The URPF makes it possible to perform fluorography with photographic monitoring and automatically selects the voltage on the anode in relation to the density of the object. (1 ref.)

- 78303 Photographic recording conditions in a diagnostic X-ray system with an image intensifier.** A.M.Yakobson, G.A.Chuiko, V.A.Marko (Flaw-Detection Res. Inst., Moscow, USSR).
Biomed. Eng. (USA), vol.16, no.4, p.120-4 (July-Aug. 1982). Translation of: *Med. Tekh. (USSR)*, vol.16, no.4, p.27-31 (July-Aug. 1982). [received: April 1983]
The authors consider the interaction between the factors that determine the informativeness of a fluorogram, and also determine the compatibility of the requirements laid down in the technical specifications for X-ray diagnostic sets as regards photographic recording. (1 ref.)
- 78304 Transmission of scattered radiation by X-ray grids.** O.B.Sokolov (Special Designs Office for Diagnostic Apparatus, Kiev, Ukrainian SSR).
Biomed. Eng. (USA), vol.16, no.4, p.125-7 (July-Aug. 1982). Translation of: *Med. Tekh. (USSR)*, vol.16, no.4, p.31-4 (July-Aug. 1982). [received: April 1983]
A cutoff grid of linear type is a basic means of preventing interference from scattered radiation in X-ray diagnosis. The author examines briefly the limiting performance of a linear grid and defines the optimum structure for a grid, which should be used in future designs. (no refs.)
- 78305 Determination of the basic parameters of PER2-3-P xeroradiographic plate.** P.D.Baltrushaitis, R.A.Kavalyauskas, V.V.Mamontov, B.K.Rakauskene (Electrography Res. Inst. & Oncology Res. Inst., Min. of Health, Vilnius, Lithuanian SSR).
Biomed. Eng. (USA), vol.16, no.4, p.128-32 (July-Aug. 1982). Translation of: *Med. Tekh. (USSR)*, vol.16, no.4, p.34-9 (July-Aug. 1982). [received: April 1983]
The authors have determined the range of working potentials for the xeroradiographic layer under practical conditions, along with the sensitivity, the relative fall in the potential in darkness, and the fatigue and they have evaluated the significance of these parameters under clinical conditions. The stability of the charging conditions has also been examined. (5 refs.)
- 78306 The GPR-1 longitudinal radioisotope gamma tomograph.** E.Yu.El'kind, V.P.Chernobrovkin, K.D.Kalantarov, Yu.M.Sidorov, V.G.Tyurin, A.L.Kangun (All-Union Res. Inst. of Medical Instrumental, Moscow, USSR).
Biomed. Eng. (USA), vol.16, no.4, p.139-42 (July-Aug. 1982). Translation of: *Med. Tekh. (USSR)*, vol.16, no.4, p.45-9 (July-Aug. 1982). [received: April 1983]
The principle of action, construction, and technical characteristics of the GPR-1 longitudinal radioisotope gamma tomograph, with analog picture formation, are described. The GPR-1 gamma tomograph is designed to obtain four longitudinal gamma tomograms and two standard gamma tomograms during each cycle of investigation. (no refs.)
- 78307 Production of a new modified type of applicator type 'Simon' with cobalt-60.** M.I.Mihajlov, T.Petkov, K.J.Mutafchiev.
Yad. Energ. (Bulgaria), no.18, p.89-93 (1983).
Cancer of the uterus is treated for some indications basically with intercavity radium therapy. A new, modified type of applicator, type 'Simon' with Cobalt-60 is proposed by the authors. The technology of production together with its advantages is given. A protective container designed and developed specially for the transportation and operation of these applicators, is described as well. (9 refs.)
- 78308 A computer program for compression of dynamic studies.** J.Verdenet, J.C.Cardot, M.Baud, A.C.Bidet (Service de Medecine Nucleaire, Lab. Biophys., CHU Besancon, France), J.Duvernoy, R.Bazin, R.Bidet.
Comput. Programs Biomed. (Netherlands), vol.16, no.1-2, p.77-82 (Feb.-April 1983).
The program described applies the well known Karhunen-Loeve transformation to the compression of the information carried by scintigraphic sequences. As a result it releases a few principal images which are associated with the dominant temporal behaviour in the sequences. The program is illustrated, and validated in the case of gated cardiac blood pool studies, mathematical and mechanical models. (8 refs.)
- 78309 A system for computer analysis of panorex radiographs.** S.D.Cook, K.A.Thomas (Dept. of Orthopaedic Surgery, Tulane Univ. Medical School, New Orleans, LA, USA), J.N.Kent.
Comput. Programs Biomed. (Netherlands), vol.16, no.1-2, p.97-104 (Feb.-April 1983).
A computer system developed for rapid analysis of panorex (panoramic) radiographs is described. Features of the system include capabilities to compare nonstandardized radiographs, and the ability to superimpose plots of a series of X-ray films. Measurements of alveolar ridge heights and comparisons at intervals in a clinical series are also performed. Simple statistics calculations can also be computed. (5 refs.)
- 78310 Cone beam convolution formula.** B.D.Smith (Radiology Dept., Hospital of the Univ. of Pennsylvania, Philadelphia, PA, USA).
Comput. Biol. & Med. (GB), vol.13, no.2, p.81-7 (1983).
Presents a three-dimensional convolution formula for a general set of cone beam data. This formula is illustrated by examining at length the formula for a particular set of cone beam data—the set of cone beam data from source points which are located along a straight line. How the three-dimensional formula could be implemented for a general set of cone data is discussed. (5 refs.)
- 78311 Rapid and accurate determination of total lung capacity (TLC) from routine chest radiograms using a programmable hand-held calculator.** R.P.C.Rodgers (Faculte de Medecine, Univ. Catholique de Louvain, Bruxelles, Belgium), R.Tannen.
Comput. Biol. & Med. (GB), vol.13, no.2, p.125-40 (1983).
Since its appearance in 1960, the method of Barnhard and associates for the determination of total lung capacity (TLC) from routine chest radiograms has been widely studied in normal and diseased subjects. The method appears to be as accurate as the current definitive procedure, total body plethysmography. The method is in routine use in major medical institutions where the procedure has been automated, but the method does not seem to have gained the wide use it deserves. This is likely due to the tedium of the technique when performed manually—a single determination can require 30 minutes. This paper presents implementation of the Barnhard method for the HP41-C hand-held programmable calculator. In conjunction with the use of a transparent reticle used for obtaining the required measurements, the program allows a single measurement to be made in under 12 minutes. (14 refs.)
- 78312 Array processors in medical imaging.** P.Alexander (Numerix Corp., Newton, MA, USA).
Computer (USA), vol.16, no.6, p.17-30 (June 1983).
Medical image processing has historically included the use of general-purpose array processors and related special-purpose high-speed computational devices. Current imaging modalities include nuclear medical imaging, computed tomography scanners, ultrasound techniques, positron emission tomography, digital radiography, and nuclear magnetic resonance. This article focuses on just

three: computed tomography, digital radiography, and nuclear magnetic resonance. These modalities represent the three techniques where the use of APs is most easily justified. (9 refs.)

78313 Filters—what metal do I use? R.F.Fleay (Dept. of Medical Phys., Royal Perth Hospital, Perth, Australia). *Radiographer (Australia)*, vol.30, no.1, p.24-6 (March 1983). The use of a heavy metal foil, namely the element erbium, is described to show that entrance skin doses to a patient can be reduced dramatically without overloading the X-ray tube. K absorption filtration techniques have a specific application and cannot be used over a wide range of kilovoltages. The selection criteria and application of erbium is described. (5 refs.)

78314 Reconstruction from sparsely sampled data by ART with interpolated rays. K.Kouris (Dept. of Phys., Univ. of Surrey, Guildford, England), H.Tuy, A.Lent, G.T.Herman, R.M.Lewitt. *IEEE Trans. Med. Imaging (USA)*, vol.MI-1, no.3, p.161-7 (Nov. 1982). [received: May 1983]

After a brief discussion of the algebraic reconstruction techniques (ART), the authors introduce the attenuation problem in positron emission tomography (PET). They anticipate that a generalization of ART, the so-called cyclic subgradient projection (CSP) method, may be useful for solving this problem. This, however, has not been successfully realized, due to the fact that data collected by the authors' proposed stationary PET detector ring are too sparsely sampled. That this is, in fact, a major problem is demonstrated by showing that ordinary ART produces reconstructions with unacceptably strong artifacts even on perfect (no attenuation) data collected according to the PET geometry. The authors demonstrate that the source of this artifact is the sparse sampling, and they propose the use of interpolated rays to overcome the problem. This approach is successful, as is illustrated by showing reconstructions from sparsely sampled data by ART with interpolated rays. (12 refs.)

78315 Undersampling errors in region-of-interest tomography. P.V.Sankar (School of Engng., Univ. of California, Irvine, CA, USA), O.Nalciglu, J.Sklansky. *IEEE Trans. Med. Imaging (USA)*, vol.MI-1, no.3, p.168-73 (Nov. 1982). [received: May 1983]

A detailed error analysis for the dual-sampling region-of-interest X-ray tomography is presented. Simulation studies are used along with a range of sampling rates to quantitate the amount of sampling errors within the region of interest. It is shown that as the rate of sampling outside the region of interest becomes sparse the amount of sampling errors within the region of interest increases considerably. (8 refs.)

78316 Streak preventive image reconstruction with ART and adaptive filtering. R.M.Rangayyan (Dept. of Electrical Engng., Univ. of Manitoba, Winnipeg, Manitoba, Canada). *IEEE Trans. Med. Imaging (USA)*, vol.MI-1, no.3, p.173-8 (Nov. 1982). [received: May 1983]

Streaks arise in computed tomograms for a variety of reasons, such as presence of high-contrast edges and objects, aliasing errors, patient movement, and use of very few views. The problem appears to be an inherent difficulty with all reconstruction methods, including backprojection (with convolution) and the algebraic reconstruction technique (ART). This paper presents the derivation and results of an ART-like algorithm (SPARTAF) oriented towards prevention of streaks via optimization of a cost function based on features of streaks, subject to the constraints of the given projection data. The object-dependent method employs pattern recognition of streaks and adaptive filtering during iterative reconstruction by ART. Results of experiments with a test pattern and of application of the method to reconstructive tomography from radiographic films are presented and the convergence properties demonstrated. (27 refs.)

78317 Super PETT I: a positron emission tomograph utilizing photon time-of-flight information. M.M.Ter-Pogossian, D.C.Ficke (Edward Mallinckrodt Inst. of Radiology, Washington Univ. School of Medicine, St. Louis, MO, USA), M.Yamamoto, J.T.Hood, Sr. *IEEE Trans. Med. Imaging (USA)*, vol.MI-1, no.3, p.179-87 (Nov. 1982). [received: May 1983]

The physical characteristics and some imaging capabilities of Super PETT I, a positron emission tomograph utilizing time-of-flight (TOF) in its image reconstruction process, were assessed experimentally by means of measurements carried out in phantoms and clinical imaging studies. The performance characteristics assessed included sensitivity, spatial resolution, image improvements resulting from time-of-flight information utilization, system dead time, and linearity. The clinical examples included imaging of the brain, the heart, the liver, and a demonstration of Super PETT I's capability of achieving cardiac gating. (14 refs.)

78318 Experimental assessment of the gain achieved by the utilization of time-of-flight information in a positron emission tomograph (Super PETT I). M.Yamamoto (Edward Mallinckrodt Inst. of Radiology, Washington Univ. School of Medicine, St. Louis, MO, USA), D.C.Ficke, M.M.Ter-Pogossian. *IEEE Trans. Med. Imaging (USA)*, vol.MI-1, no.3, p.187-92 (Nov. 1982). [received: May 1983]

The gain achieved in image quality by utilizing, in the image forming process, the time-of-flight information (TOF) of positron annihilation photons between their inception and detection was measured experimentally by means of a positron emission tomograph (PET)-Super PETT I. The measurements were carried out by imaging a 35 cm cylindrical uniform phantom containing different positron activity concentrations. The gain achieved through the incorporation of TOF information, defined as the ratio of variances in images reconstructed with and without TOF information, was found to be approximately 3 at the lowest activity concentration and 5-8 in the activity concentration range typically encountered in clinical studies, especially in fast or dynamic studies. This increase in gain with activity was interpreted as resulting from the reduction of random coincidences when TOF information is used. Further image improvement is yielded by incorporating TOF information into the PET attenuation correction provided by the measurement of transmission of annihilation photons in the object imaged. (17 refs.)

78319 An improved algorithm for reprojecting rays through pixel images. P.M.Joseph (Dept. of Diagnostic Radiology, Univ. of Maryland, Baltimore, MD, USA). *IEEE Trans. Med. Imaging (USA)*, vol.MI-1, no.3, p.192-6 (Nov. 1982). [received: May 1983]

It is often desired to calculate line integrals through a field of reconstructed CT density pixels for the purpose of improving CT image quality. Two algorithms widely published and discussed in the past are known to either degrade spatial resolution or generate errors in the results due to the discontinuous 'square pixel' modeling of the reconstructed image. An algorithm is described, based on linear interpolation between pixels, which provides superior accuracy without unnecessary loss of resolution. It was tested on simulated data for a head section and on a narrow Gaussian density distribution. The experimental results demonstrated improved performance. The

method is expected to prove useful for many types of post-reconstruction processing, including beam hardening, missing data, and noise suppression algorithms. (26 refs.)

78320 Errors in isocenter of Picker C-9000 teletherapeutic unit. F.J.Bova, L.T.Fitzgerald (Univ. of Florida Coll. of Medicine, Gainesville, FL, USA).

Health Phys. (GB), vol.44, no.5, p.553-4 (May 1983). In routine maintenance of the authors' Picker C-9000 ⁶⁰Co teletherapy unit, the isocentric stability was checked by mapping the movement of the front pointer, light field projection, and radiation field as the unit rotated about its isocenter. The original specifications for the unit upon installation (1966) set the limit of the deviations from isocenter to plus or minus 2 mm. It has recently become evident that the isocentricity of the unit does not meet this tolerance. The errors described are clinically significant and have forced the authors to use the unit for nonisocentric techniques only. It is recommended that whenever these units are checked for isocentric stability, that points significantly above or below isocenter be examined for coincidence of not only the mechanical and light field, but also the radiation field, to ensure that compensating errors are not inadvertently overlooked. (1 ref.)

78321 Image reconstruction from list-mode data in an emission tomography system having time-of-flight measurements. D.L.Snyder, D.G.Politte (Washington Univ., St. Louis, MO, USA).

IEEE Trans. Nucl. Sci. (USA), vol.ns-30, no.3, p.1843-9 (June 1983). List-mode data collected in a positron-emission tomography system having time-of-flight measurements are three dimensional, but all algorithms which have been published to date operate on two-dimensional data derived from these three-dimensional data. The authors argue that additional information present in 3-D data is useful for reconstruction of images. (13 refs.)

78322 Reconstruction from limited angular projection data using constrained optimization. H.Katsulai, N.Arimizu (Dept. of Radiology, Faculty of Medicine, Chiba Univ., Chiba, Japan). *IEEE Trans. Nucl. Sci. (USA)*, vol.ns-30, no.3, p.1870-9 (June 1983).

A new type of pixel decomposition is introduced to suppress modeling noise and then an algebraic method is developed for reconstruction from limited angular projection data. The basic idea with this method is to directly control the tradeoff between resolution and noise, taking into account the uncertainty of the discrepancy criterion generally used in an algebraic method for reconstruction. The results of a simulation using a simple mathematical phantom are also presented, demonstrating the effectiveness of this method. (8 refs.)

78323 Experimental results of the dichotomic sampling in circular ring positron emission tomograph. Z.H.Cho, S.K.Hilal, J.B.Ra, K.S.Hong, H.S.Lee (Korea Advanced Inst., of Sci., Seoul, Korea), R.E.Bigler. *IEEE Trans. Nucl. Sci. (USA)*, vol.ns-30, no.3, p.1892-8 (June 1983).

Experimental verification of the new dichotomic sampling scheme was attempted and applied to a circular ring PET system. Two different types of aperture collimators were adopted for high resolution (HR) and very high resolution (VHFR) imaging. In HR mode, a resolution of 6.5 mm FWHM was obtained without appreciable degradation in overall sensitivity. In phantom studies with HR mode a sensitivity of 4500 counts/sec/μCi/cc was obtained for a 20 cm diameter uniform phantom filled with water. (25 refs.)

78324 Enhancement of nodular lesions in CT liver scans. R.L.Webber, A.Dwyer, H.Cramer, M.Putterman. *J. Clin. Eng. (USA)*, vol.8, no.1, p.69-79 (Jan.-March 1983).

The impact of selected image-processing schemes on diagnostic performance obtainable from computer-processed CT scans containing simulated nodular lesions was determined from controlled radiological observations. Normal CT scans of the upper abdomen were processed by a computer to simulate the presence of a randomly-located, disk shaped, low-contrast, nodule within the liver stroma. Results for selected enhancement techniques were tallied using a balanced experimental design. The data indicate that suitably processed displays significantly improved diagnostic performance expressed in terms of diagnostic errors, information transfer, and the implied noise relative signal strength, d'. The same mode of display significantly reduces the time required in making diagnostic decisions relative to the status quo. (11 refs.)

78325 Cardiac blood pool emission tomography. R.Itti, L.Philippe, J.M.Lorgeron, B.Charbonnier, P.Raynaud, M.Brochier (Services de Médecine Nucleaire et de Cardiologie, CHU Trousseau, Tours, France). *J. Biophys. & Med. Nucl. (France)*, vol.7, no.1, p.7-10 (1983). In French.

After blood pool labeling using technetium-99 m, a series of cardiac pictures is acquired during the rotation of a gamma-camera about the patient. Computer processing leads to reconstruction of various tomographic slices from the original planar projections. Electrocardiographic gating selects the different phases of the cardiac cycle. Individual slices through the left ventricular region are added in order to provide 'thick' slices on which global and regional parameters of the left ventricular function can be determined. Due to the proportionality existing between count rates and labeled blood volumes, any geometrical model can be avoided. The delineation of regions of interest for count integration is made easier due to the absence of superimposition of structures; no correction for background is necessary. Tomography thus appears to be more consistent and more accurate than the classical methods using planar projections. In addition, right ventricular morphological and kinetic studies can be performed in the same conditions as for the left ventricle. (4 refs.)

78326 Lung exploration by SPECT current status and perspectives. D.J.Macey, R.Marshall (Dept. of Radiation Phys. & Chest Diseases, Churchill Hospital, Oxford, England). *J. Biophys. & Med. Nucl. (France)*, vol.7, no.1, p.11-19 (1983).

If SPECT of the lung is to be introduced as a routine clinical procedure the additional information provided must justify the complexity of the test. The transverse section images must depict adequately the relative distribution of a radiopharmaceutical in the lungs. For the thorax in particular, where there is a comparatively large spread of attenuation coefficients from lung to bone density, the use of a single mean attenuation coefficient must be validated. A rotating gamma camera system for SPECT of the lung uses standard doses and radiopharmaceuticals and only requires a modest addition to the capital cost of a computerised gamma camera facility. The present SPECT systems improve the depth resolution with some degradation of the conventional X and Y resolution but in view of the movement of the heart and lungs with respiration the spatial resolution is about 2 cm FWHM in three dimensions. The authors have used a transmission-emission method to check the accuracy of SPECT images of the lung perfusion scan. The correct total number of counts in the transverse slices can be determined by the transmission-emission method and the resultant images are the best description of the distribution of activity in the lungs. With SPECT of the lung transverse section images can be obtained which are qualitative on a relative and absolute scale. (16 refs.)

78327 Performance and quality control of scintillation cameras. J.L.Moret, D.Iachetti (Lab. de Biophys. Experimentale, CHU, Henri-Mondor, Creteil, France), J.F.Brandon, G.Pascal, E.Sachot, J.Legrand, A.Lansari, L.Guerin, A.Desgrez, G.Meyniel, B.Mensch, J.Mensch, F.Therain, F.Soussaline, D.Barre, G.Taunay.

J. Biophys. & Med. Nucl. (France), vol.7, no.1, p.43-57 (1983). In French. Acceptance testing, quality and control assurance of gamma-cameras are a part of diagnostic quality in clinical practice. Several parameters are required to achieve a good diagnostic reliability: intrinsic spatial resolution, spatial linearity, uniformities, energy resolution, count-rate characteristics, multiple window spatial analysis. Each parameter was measured and also estimated by a test easy to implement in routine practice. The instrumentation required was a 4028 multichannel analyzer linked to a microcomputer, minicomputers and a set of phantoms. Several tests proposed by NEMA and WHO have to be improved concerning too punctual spatial determinations during distortion measurement with a multiple window. Contrast control of image needs to be monitored with a high counting rate. This study shows the need to avoid punctual determinations and the value of giving sets of values of the same parameter for the whole field and to report mean values with their standard variation. (48 refs.)

78328 Geometric determination of left ventricular volume from gated blood-pool studies using a slant-hole collimator. R.F.Uren, H.N.Newman, B.F.Hutton, J.Cormack, L.Bernstein, L.Allen, I.Dyer (Dept. of Nuclear Medicine, Royal Prince Alfred Hospital, Camperdown, NSW, Australia).

Radiology (USA), vol.147, no.2, p.541-5 (May 1983). A geometric method of measuring absolute left ventricular volumes from gated blood-pool studies obtained in a single-plane modified left anterior oblique view was evaluated prospectively in 30 patients who also underwent single-plane contrast ventriculography. The gated studies used a 30° straight-bore slant-hole collimator with the holes slanted caudally. Left ventricular end-diastolic volume was calculated using the area-length method, with semiautomatic definition of the left ventricular region of interest and the maximum length of the left ventricle. Ejection fraction was determined from the left ventricular time activity curve. The left ventricular end-systolic volume was derived using the end-diastolic volume and ejection fraction. Correlation coefficients between the two methods were 0.93 for end-diastolic volume, 0.95 for end-systolic volume, and 0.91 for ejection fraction. This method provided accurate and highly reproducible measurements of actual left ventricular volumes and was easily applicable in routine clinical studies. (17 refs.)

78329 An improved method of estimating the portal venous fraction of total hepatic blood flow from computerized radionuclide angiography. R.Sarper, Y.A.Tarcan (Dept. of Radiology, Emory Univ. School of Medicine, Atlanta, GA, USA).

Radiology (USA), vol.147, no.2, p.559-62 (May 1983). The measurement of portal venous flow of the liver is important in the evaluation of patients for shunt surgery. A previous report (see R. Sarper et al., *ibid.*, vol.141, p.179-84, 1981) described a method using slope analysis of hepatic radionuclide angiograms to generate an index of relative portal flow, which correlated well with angiographic grades of portal perfusion. The present report describes a refinement in bolus administration and a modification in technique that appear to reflect true portal venous flow more accurately. A total of 109 studies was performed, including seven normal and 80 cirrhotic patients. The method was reproducible ($r=0.998$) and showed good correlation with the angiographic grades of perfusion ($r=-0.906$). (4 refs.)

78330 Physical and clinical evaluation of new high-strip-density radiographic grids. K.Doi, P.H.Frank, Heang-Ping Chan, C.J.Vyborny, S.Makino, N.Iida, M.Carlin (Dept. of Radiology, Univ. of Chicago, Chicago, IL, USA).

Radiology (USA), vol.147, no.2, p.575-82 (May 1983). The imaging performance of new high-strip-density (HSD) grids having 57 lines/cm was compared with that of conventional low-strip-density (LSD) grids having 33 or 40 lines/cm. The unique advantage of HSD grids is that, under most standard radiographic conditions, the grid lines are not noticeable on the final image, even if the grid is stationary. This is due to the combined effect of the high fundamental spatial frequency of HSD grids, the modulation transfer function of screen-film systems and of the human visual system, and scattered radiation. Monte Carlo simulation studies, phantom images, and clinical evaluation indicate that HSD grids can provide contrast improvement factors and Bucky factors that are comparable with or slightly better than those obtained with LSD grids. Therefore, it may now be possible to eliminate moving Bucky trays from radiographic tables and fluoroscopic devices. (7 refs.)

78331 Materials and method of certification of standard specimens for checking computerized X-ray tomographs. E.I.Vainberg, I.A.Kazak, V.P.Kurozaev, G.Z.Plotkina (Sci.-Res. Inst. of Introscopy, Moscow, USSR). *Sov. J. Nondestr. Test. (USA)*, vol.18, no.9, p.672-7 (Sept. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.9, p.7-14 (Sept. 1982). Groups of organic materials of a standardized elemental composition and method of certifying standard specimens for checking computerized X-ray tomographs with a certain mass density by a standardized method are recommended. 87.60M Radiation dosimetry

78332 Hungarian-Austrian co-operation in radiation dosimetry. K.Zsanzs (Nat. Office of Measures, Budapest, Hungary), K.E.Dufschmid. *Acta Phys. Acad. Sci. Hung. (Hungary)*, vol.52, no.3-4, p.265-74 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981). Since 1974 a close and fruitful co-operation has been in progress between the Hungarian National Office of Measures (OMH) and the Austrian Research

Center Seibersdorf in the field of radiation dosimetry. The work began with intercomparison measurements and calibration of dose meters at OMH. The practical experiences gained at OMH have been applied in the design of the new Austrian dosimetry laboratory established between 1975 and 1977. Since 1976 the cooperation of the two Institutions has been included in the Hungarian-Austrian inter-governmental agreement on technical-scientific co-operation as a joint priority dosimetry standard and the calibration facilities in both countries. (7 refs.)

78333 Radiation exposure and associated cancer risk due to radon and decay products. E.Pohl, F.Steinhauser, W.Hofmann, J.Pohl-Ruling (Div. of Biophys., Univ. of Salzburg, Salzburg, Austria). *Acta Phys. Acad. Sci. Hung. (Hungary)*, vol.52, no.3-4, p.291-6 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981).

The atmospheric content of radon and its decay products, especially in buildings, represents a significant contribution to the radiation exposure of a man even in a normal environment. A study in Salzburg-City/Austria over several years was carried out in over 1000 working-, living- and bedrooms. Dose calculations were performed on 729 test persons, considering individual differences in age, sex and life-style and atmospheric nuclide concentration at different sites. Induction of lung cancer caused by inhalation of radon and its decay products was correlated with cumulative exposure based on experience with lung cancer incidence amongst uranium miners. It was shown for Salzburg City that 15 to 35% of the observed number of lung cancer cases may be induced by radon and its decay products, although Salzburg is an area with a 'normal' natural radioactive environment. (12 refs.)

78334 Stochastic aspects of lung dosimetry for radon decay products at low dose levels. W.Hofmann (Div. of Biophys., Univ. of Salzburg, Salzburg, Austria).

Acta Phys. Acad. Sci. Hung. (Hungary), vol.52, no.3-4, p.297-302 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981).

The determination of upper limits for the amount of inhaled radon decay products needs detailed information on the resulting radiation dose in different organs and tissues, particularly in the respiratory tract. The common procedure of theoretical lung dosimetry is characterized by applying simple analytical techniques to a data base consisting of mean values for all anatomical and physiological parameters involved. However, it is well known that great inter- as well as intra-subject variabilities of lung dimensions and clearance processes could be observed, questioning, therefore, the applicability of simplified anatomical and clearance models. Substituting the mean values by probability distributions and applying Monte Carlo techniques a dosimetric method for determining lung doses is presented, taking into consideration these variabilities. A second source of fluctuations in lung dosimetry is caused by the randomness of nuclide distributions, lung tissue structure and stochastic energy absorption in lung cells. (5 refs.)

78335 Quantitative profile scanning, a means for internal dose assessment. A.Andrasi, E.Beleznay (Health Phys. Dept., Central Res. Inst. for Phys., Budapest, Hungary).

Acta Phys. Acad. Sci. Hung. (Hungary), vol.52, no.3-4, p.303-10 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981).

A combined measuring and computing method is given by means of which the Committed Effective Dose Equivalent can be estimated. A sensitive detector equipped with a suitable collimator moving along the length of a person being investigated, enables the count rate profile to be obtained from which organ activities can be deduced. With repeated measurements the activity time variations and their time integrals can be derived, the latter being proportional to the organ doses. The general description of the methods and its implementation in the radiation protection practice of the Central Research Institute for Physics is given. Test experiments show the method to be suitable for internal dose assessment when the activity exceeds 0.5 kBq per organ. (8 refs.)

78336 Retrospective evaluation of occupational annual doses received by workers producing radioactive sources. I.Bojtor ('Frederic Joliot-Curie' Nat. Res. Inst. for Radiobiology & Radiohygiene, Budapest, Hungary), F.Golder, M.Osavy, E.Bobok.

Acta Phys. Acad. Sci. Hung. (Hungary), vol.52, no.3-4, p.311-16 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981).

Personal dosimetric data from external radiation recorded during a 19-year period at the Institute of Isotopes were subjected to extensive computer analysis to examine the applications of the relevant ICRP dose limitation system by following the trend of radiation exposures and estimating the risk levels for various occupational fields. Based on the values of the average annual dose equivalents and Ω obtained from the whole observation period, even the most exposed group of maintenance, packaging and transportation workers can be classified as belonging to working category 'B' of UNSCEAR, thereby permitting the conclusion that working conditions at the Institute are satisfactory. The average annual dose equivalents in time intervals of employment were found to decrease with increased time spent doing the same work. The risk levels were estimated from 25-year-lifetime doses by using 'time-related' average annual doses. The risk for the highest exposed group (workers in maintenance, packaging and transportation) was assessed to be $1.2 \cdot 10^{-3}$ fatalities per working lifetime. It may be concluded that in each occupational group of the Institute the mortality risk of radiation-induced cancer is lower than the hazards in non-radiation occupations having high standards of safety. (11 refs.)

78337 Determination of the energy response of dosimeters with a Bragg-monochromatized beam. N.Vana, H.Aiginger (Atomic Inst. of Austrian Univs., Vienna, Austria).

Acta Phys. Acad. Sci. Hung. (Hungary), vol.52, no.3-4, p.333-9 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981).

In the energy region below 50 keV the energy response of dosimeters is usually determined by means of filtered Bremsstrahlung radiation. The 'monochromatic' radiation produced by filtering the continuous X-ray spectrum of an X-ray tube shows a broad energy distribution for the maximum of the intensity and a considerable 'tail' to low energies. To avoid this disadvantage a Bragg monochromator is used for the energy region between 10 keV and 50 keV. The Bragg monochromator, a commercially available X-ray spectrometer, reflects selectively monochromatic X-rays from a continuous bremspectrum of a tungsten X-ray tube. The angle of reflection and the energy are determined by the Bragg condition. The energy resolution obtained was 2%. The photon flux density at the place of the dosimeter was measured with an efficiency calibrated Ge(Li) semiconductor detector. From this photon flux density the actual exposure of the dosimeter under examination can be calculated. (4 refs.)

- 78338 Measurement of the energy response of LiF, CaF₂ and CaSO₄ TL-dosimeters.** N.Vana, H.Aiginger, W.Erath, T.Michev (Atomic Inst., Austrian Univs., Vienna, Austria). *Acta Phys. Acad. Sci. Hung. (Hungary)*, vol.52, no.3-4, p.341-5 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981). The most important materials used in thermoluminescence dosimetry (TLD) are LiF, CaF₂ and CaSO₄ with various dopants. LiF:Mg, Ti is almost tissue equivalent and therefore the most applied TLD-material in personnel and medical dosimetry. CaF₂:Dy offers the highest sensitivity of the above mentioned materials and is used in environmental and low-dose dosimetry. CaSO₄:Dy can easily be labor made and is the cheapest phosphor. As the effective atomic numbers of CaF₂ and CaSO₄ differ markedly from that of tissue material the response curve of both materials must be carefully determined in the energy range dominated by the photoeffect. The energy responses of these three listed phosphors were determined by means of a Bragg monochromator, filtered radiation from a gold target bombarded by electrons from a Van de Graaff accelerator, the radiation of a ¹³⁷Cs-source (662 keV) and a ⁶⁰Co-source (1.17, 1.33 MeV). The response-energy dependence of the three dosimeters shows maxima at 35 keV (LiF and CaF₂) and 40 keV (CaSO₄). (4 refs.)
- 78339 Lithium drifted beryllium oxide high sensitivity thermoluminescent dosimeter.** S.Makra (Nat. Oncological Inst., Budapest, Hungary). *Acta Phys. Acad. Sci. Hung. (Hungary)*, vol.52, no.3-4, p.353-6 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981). A new BeO:Li detector sensitized by a novel method is described. The glow curve of the detectors shows two peaks, the ratio of peak heights depends on dose. The light output per unit dose slightly exceeds that of lithium fluorides. Reproducibility is $\pm 2\%$ for doses higher than 3 mGy, detection limit is 50 μ Gy, exceeding by two-three order of magnitude the values obtained for commercial BeO detectors. Response shows less than $\pm 15\%$ change with photon energy. Fading is lower than 2% per months. (8 refs.)
- 78340 Estimation of per caput dose and collective dose from the use of Danube water.** M.Tschurlovits (Atomic Inst., Austrian Univs., Vienna, Austria). *Acta Phys. Acad. Sci. Hung. (Hungary)*, vol.52, no.3-4, p.413-17 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981). Deals with methods for assessment of both per caput and collective dose resulting from the use of the water of the Danube river, where drinking water and fish consumption pathways are considered. Results of previous measurements are used as basis for the estimation. It was found that the dose from natural radionuclides considerably exceeds the dose from artificial radionuclides. (7 refs.)
- 78341 The radiation dose from coal burning: a review of pathways and data.** J.O.Corbett (Berkeley Nuclear Labs., CEGB, Berkeley, England). *Radiat. Prot. Dosim. (GB)*, vol.4, no.1, p.5-19 (1983). All stages of the coal fuel-cycle, including mining, combustion and utilisation or disposal of the ash, cause minor perturbations of the natural radiation environment. Many radiological assessments of this effect have already been made, often for comparison with nuclear power, though few have considered the cycle as a whole. This review is an attempt to cover as broadly as possible the various environmental pathways leading to radiation dose in man, and to identify and summarise the sources of relevant data. Although local variations may be very significant, the resulting doses are normally only a small fraction of the natural background. Collective doses to the population arise primarily through inhalation of radioactivity in ash emitted from chimneys and through ingestion in food after deposition on crops and pasture or in the sea. On a global scale, there is a comparable reduction in collective dose due to the dilution of atmospheric carbon-14 by stable carbon dioxide emission. Two less familiar effects, the occupational dose to miners and the population dose from the use of ash in building materials, should also be taken into account, but their proper assessment depends on what alternative occupation or material is chosen for comparison; the net effects can be either positive or negative. Although the nuclear fuel cycle is briefly discussed, it is argued that comparisons between radiation doses from coal burning and nuclear power are of limited value. (103 refs.)
- 78342 Statistical characterisation of a critical group.** M.Tschurlovits (Atominst. of Austrian Univs., Wien, Austria), D.Beninson. *Radiat. Prot. Dosim. (GB)*, vol.4, no.1, p.27-31 (1983). A proposal is made to separate a possible critical group from the remaining exposed group. The basic assumption is that the distribution of doses, both in the general exposed group and in the critical group, can be described by statistical distribution functions. It is proposed that when no clear identification of the critical group is feasible, the 5% higher end of the dose distribution in the candidate exposed population group is selected as the critical subgroup, and that the average dose in that 'tail' can be used for limitation purposes. The actual dose distribution or parts of it must be determined by appropriate monitoring or modelling procedures. (10 refs.)
- 78343 Specific activity estimation of minerals and other materials containing natural radionuclides.** W.A.Kolb (Phys.-Tech. Bundesanstalt, Braunschweig, Germany). *Radiat. Prot. Dosim. (GB)*, vol.4, no.1, p.33-6 (1983). Most radiation protection regulations and codes define limits on gross specific activity below which radiation protection measures are not required. The question arises as to which radionuclides contained in a sample have to be taken into account in calculating the gross activity. This paper considers natural radionuclides according to their radiotoxicity and relative dose contributions and suggests criteria against which radiological relevance can be judged. Several examples of naturally occurring materials are discussed. (11 refs.)
- 78344 The use of solid-state nuclear track detectors in radiation dosimetry, medicine and biology.** S.A.Durrani (Dept. of Phys., Univ. of Birmingham, Birmingham, England). *Nucl. Tracks & Radiat. Meas. (GB)*, vol.6, no.4, p.209-28 (1982). The author briefly surveys the applications in radiation protection and life sciences. The major emphasis is on the use of plastic track detectors for the dosimetry of neutrons, both thermal and fast. Alpha particle dosimetry is also considered, with special emphasis on radon measurements in houses. Both active and passive dosimeters are briefly considered. A few typical and representative examples of the application of SSNTDs in the medical and radiobiological fields are next presented. These encompass the filtration of malignant cells in blood, the measurement of α -emitters in the environment, and the distribution of lead in teeth and bones. Finally a very brief review of some automatic and semi-automatic methods of scanning normal or electrochemical etching of the plastic detectors, is given. (43 refs.)

- 78345 Time-dose-fractionation.** P.Drake. *Radiographer (Australia)*, vol.30, no.1, p.5-9 (March 1983). The time-dose-fractionation (TDF) system has been researched, used and evaluated in the authors' clinic since May 1981. Since August 1981 it has been used routinely in all dosage calculations. There has only been a limited amount of iso-effect planning, due, mainly, to a lack of time to plan in dual modes. This paper is the synthesis of that research, use and evaluation. It has been demonstrated that the TDF method overcomes most of the obstacles currently faces. It is a consistent, reliable technique which lends itself to future analysis. If the method was widely accepted and used there would exist a legitimate means of intercomparison. This could lead, ultimately, to a far better understanding of radiobiology and its clinical implications. (25 refs.)
- 78346 Estimation of shallow-dose equivalent using a two-element dosimeter.** V.P.Gupta (EG&G Idaho Inc., Idaho Nat. Engng. Lab., Idaho Falls, ID, USA). *Health Phys. (GB)*, vol.44, no.4, p.373-8 (April 1983). Estimation of shallow-dose equivalent using a two-element dosimeter is described under the guidelines of a standard adopted by the Health Physics Society Standards Committee and the dosimetry practices followed by most dosimeter processors. This standard is to be used in a future mandatory testing program in the US. A mathematical formulation, correlating dosimeter response and 'shallow-dose equivalent factors' at different energies, is presented. A thermoluminescent dosimeter (TLD), currently used at the author's institute, is examined for determining shallow-dose equivalent response and the results are discussed for beta as well as photon responses. (16 refs.)
- 78347 Depth-dose curves for ⁹⁰Sr and natural and depleted uranium in Mylar.** R.L.Coleman, C.G.Hudson, P.A.Plato (Tennessee Valley Authority, Health Phys. Services, Muscle Shoals, AL, USA). *Health Phys. (GB)*, vol.44, no.4, p.395-402 (April 1983). Describes the generation of accurate depth-dose curves in Mylar for ⁹⁰Sr and slabs of natural and depleted uranium from 0 to 1000 mg/cm², utilizing an extrapolation chamber. The absorbed dose rate produced by natural uranium was found to decrease from 235 mrad/hr at a depth of 7 mg/cm² to 43 mrad/hr at 300 mg/cm² to 4.8 mrad/hr at 1000 mg/cm². The dose rate produced by depleted uranium was found to decrease from 205 mrad/hr at 7 mg/cm² to 34 mrad/hr at 300 mg/cm² to 2.3 mrad/hr at 1000 mg/cm². A 1-mCi extended area ⁹⁰Sr source (encapsulated in 50 mg/cm² Ag) was found to produce an absorbed dose rate of 16997 mrad/hr at 57 mg/cm², 5000 mrad/hr at 300 mg/cm², and 27.1 mrad/hr at 1050 mg/cm². Doses to deep organs determined historically at depths ranging from 300 to 1000 mg/cm². The results of this study show that ⁹⁰Sr and uranium produce significant absorbed dose rates at a depth of 300 mg/cm². Thus, if doses for deep depths are determined at 300 mg/cm² for mixed β - γ exposures, the dose will be overestimated due to the presence of the β component. (13 refs.)
- 78348 Biologically and physically recorded doses after an accidental exposure to ⁶⁰Co- γ rays.** G.Stephen, W.Hadnagy, C.Hammermaier, U.Imhof (Inst. fur Strahlenhygiene des Bundesgesundheitsamtes, Neuberberg, Germany). *Health Phys. (GB)*, vol.44, no.4, p.409-11 (April 1983). Reports an accidental exposure of two individuals who received fairly homogeneous whole-body doses of ⁶⁰Co- γ rays. Chromosome analyses were performed 103 days after the accident in the other. From time correction factors, biological doses were estimated and compared with physically calculated doses and those recorded from the film badges. (11 refs.)
- 78349 RADOK: an integrating, passive radon monitor.** M.Annanmaki, H.Koskela, M.Koponen, O.Parvainen (Inst. of Radiation Protection, Helsinki, Finland). *Health Phys. (GB)*, vol.44, no.4, p.413-16 (April 1983). A passive, integrating radon monitor with characteristics suitable for mine surroundings has been constructed. This monitor is based on the principle of electrostatic collection of radon daughters. The detection system has been adapted from the Alphameter-400. (2 refs.)
- 78350 Mucosal structure and radon in head carcinoma dosimetry.** R.A.Schlenker (Centre for Human Radiobiology, Argonne Nat. Lab., Argonne, IL, USA). *Health Phys. (GB)*, vol.44, no.5, p.556-62 (May 1983). The investigation reported shows that: (1) The location of the epithelial cells implied by ICRP Publication 26 is incorrect. It leads to dose rates from bone and to dose rate ratios which are much too high. (2) Epithelial thickness has little effect on the ratio of dose rates. (3) The dose rate ratio is strongly dependent on the thickness of the lamina propria and would depend strongly on the thickness of the cytoplasm layer if direct nuclear hits were required for cell transformation. (4) Based on the limited data available for lamina propria and epithelial thicknesses, the air-spaces would probably be the dominant source of dose in the mastoid air cells if the ratio of radioactivity levels in bone and airspace were no more than 1.1/g. This would be true whether targets were spread throughout the whole cell or confined to the nucleus alone. (9 refs.)
- 78351 A virtual-nuclides method for whole-body counting and quality control.** Mao-Hsiung Chen (Inst. of Electronics, Nat. Chiao-Tung Univ., Hsinchu, Taiwan), Pao-Shan Weng. *Health Phys. (GB)*, vol.44, no.5, p.562-6 (May 1983). Whole-body counting using NaI(Tl) detectors is discussed. A radionuclide analysis method based on the matrix method is described. Minimum detectable activities are considered. (9 refs.)
- 78352 Neutronspektrum es dozisoszlas vizsgalatok szamitassal es mersel elliptikus fantomban ²⁵²Cf es nehezvizvel moderalt ²⁵²Cf neutron forrasokra** (Neutron spectra and dose distribution calculations and measurements for a filled elliptical phantom using bare and heavy-water moderated ²⁵²Cf neutron sources). J.Palfalvi. Report KFKI-1983-47, Hungarian Acad. Sci., Budapest (1983), 18 pp. In Hungarian. Calculations and measurements for the dose distribution in a water-filled elliptical phantom when irradiated with neutrons of a bare and a heavy water moderated californium neutron sources are presented. The calculations were performed by a Monte Carlo code, and different nuclear track detectors were used for the measurements. (11 refs.)

87.60P Radiation protection
(inc. radiation monitoring)

78353 A secondary standard dosimetry system for calibration of radiation protection instruments. K.E.Duftschmid (Austrian Res. Center Seibersdorf, Seibersdorf, Austria), J.Hizo. *Acta Phys. Acad. Sci. Hung. (Hungary)*, vol.52, no.3-4, p.275-82 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981). In view of the increasing need and accuracy requirements for the calibration of radiation protection dosimeters, a novel secondary standard system consisting of a low level ionization chamber with 10^4 cm^3 sensitive volume operating at ambient atmospheric pressure and an automated digital current integrator with dose/dose rate calculation has been designed. The spherical ionization chamber of 27 cm diameter and 3 mm wall thickness is made from high pressure extruded polyacetal resins (CH_2O), providing a rugged structure of excellent long term stability of sensitive volume combined with extremely flat energy response. The wall thickness of the chamber is sufficient for secondary electron equilibrium up to several MeV of photon radiation without additional build-up-caps, etc. (3 refs.)

78354 The role of radioactivity standard reference materials in Hungarian health physics practice. A.Szorenyi (Nat. Office of Measures, Budapest, Hungary). *Acta Phys. Acad. Sci. Hung. (Hungary)*, vol.52, no.3-4, p.283-9 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981). Radioactivity Standard Reference Materials (RSRMs) have been issued by the National Office of Measures (OMH) for more than ten years. At the present time OMH offers various solutions and solid standards for over 50 radionuclides. The interest in RSRMs has especially increased since 1976 after the issue of the Government Decree of Measures. The author shows the role of RSRMs by several examples in radiation protection of nuclear power plants and in nuclear medicine. Suitable absolute and relative methods and equipment have been developed for the activity determination of RSRMs of very different forms. The equipment and their most important parameters are briefly reviewed. (6 refs.)

78355 TLD measurements with LiF and $\text{CaSO}_4\text{:Tm}$. P.P.Szabo (Central Res. Inst. for Phys., Budapest, Hungary). *Acta Phys. Acad. Sci. Hung. (Hungary)*, vol.52, no.3-4, p.323-31 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981). LiF chips of Polish origin used for personnel monitoring at the author's Institute are planned to be used at the Paks Nuclear Power Station, (Hungary). The thermal and intermediary neutron sensitivities of the LiF chips were established. In environmental monitoring, Hungarian $\text{CaSO}_4\text{:Tm}$ TLDs are used in tandem: one being heavily, the other being slightly filtered. In this way not only the dose but also the low energy contribution of terrestrial radiation can be established. The system was tested in International Intercomparisons. Certain other dose rate dependence measurements of $\text{CaSO}_4\text{:Tm}$ in the literature are questionable, leading to the conclusions of TLD reader instability. (34 refs.)

78356 Investigations on microwave radiation exposure. T.Predmerszky, L.Ballay, E.Boloni, L.D.Szabo, L.Vamos ('Frederic Joliot-Curie' Nat. Res. Inst. for Radiobiology & Radiohygiene, Budapest, Hungary). *Acta Phys. Acad. Sci. Hung. (Hungary)*, vol.52, no.3-4, p.479-86 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981). The extensive use of microwave devices calls for the radiation control of equipment, work places and environment also in Hungary. Because of the lack of comprehensive knowledge about the biological effects of microwaves there exist no internationally accepted safety standards. The power density values measured at work places seldom exceed the level of $100\text{ }\mu\text{W}/\text{cm}^2$ recommended in Hungary. Investigations were made with humans and animals. Several persons working in telecommunication for more than five years complained of headache, fatigue, irritability and some vegetative symptoms, but no expressed health damage was observed. Experiments on animals supplied new data about the thermal effects of microwaves on embryos, including effects on liver and brain. To solve the problems of microwave radiation protection Hungarian researchers have started interdisciplinary cooperation. (6 refs.)

78357 Development of protection against radiation in Austria during the past decade. J.K.Hohenberg (Bundesmin. fur Soziale Verwaltung, Wien, Austria). *Acta Phys. Acad. Sci. Hung. (Hungary)*, vol.52, no.3-4, p.317-21 (1982). In German. [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981). Describes the work of Austrian authorities concerned with protection against radiation including the annual checks of equipment and of exposed personnel. Tables show the numbers of medically examined employees found unsuitable for exposure to radiation (28 out of 7100 in 1979) and the number of persons reported to be injured by radiation (2 per year from 1976 to 1979). (no refs.) J.S.

78358 Building designs permitted according to the Austrian Radiation Protection Act. J.K.Hohenberg (Bundesmin. fur Soziale Verwaltung, Wien, Austria). *Acta Phys. Acad. Sci. Hung. (Hungary)*, vol.52, no.3-4, p.475-37 (1982). In German. [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981). Explains that the dose output of enclosed radioactive materials must not exceed 10^{-6} Sv/h at a distance of 10 cm, according to Austrian law, unless a special permit has been issued (e.g. equipment used in dentistry, materials for non-destructive testing, smoke detector, thickness measuring instruments, level gauges). (no refs.) J.S.

78359 Radiation monitors measure potential health hazards. J.Browne. *Microwaves & RF (USA)*, vol.22, no.3, p.121-8, 154 (March 1983). Like many other phenomena once dismissed as harmless, nonionizing radiation is now considered a potential health hazard at certain power levels. The author describes radiation monitors, which were once extremely narrow-band devices intended expressly for leak detection in microwave ovens, and which have blossomed into extremely sensitive, broadband devices capable of measuring near-and far-field nonionizing radiation at frequencies as high as 40 GHz. Most modern radiation monitors are similar in appearance and consist of a diode-based detection probe connected directly or via coaxial cable to a measurement meter. (3 refs.)

78360 Diagnostic X-ray shielding design based on an empirical model of photon attenuation. B.R.Archer, J.L.Thornby, S.C.Bushong (Baylor Coll. of Medicine, Houston, TX, USA). *Health Phys. (GB)*, vol.44, no.5, p.507-17 (May 1983). A series of nomograms that simplify determination of diagnostic X-ray shielding requirements with lead are presented. All recommendations of the NCRP, except that to 'add one half value layer (HVL)' in determining secondary barriers, were followed in the production of these curves. For secondary barriers, the shielding required to reduce the weekly exposure to the applicable maximum permissible dose has been determined. This eliminates the over-shielding inherent in the 'add one HVL' approximation and allows a variety of more cost effective materials to be considered for secondary barriers. (15 refs.)

78361 Shielding device for brachytherapy sources. A.J.Schneider, H.S.Clarke (Dept. of Radiology, Medical Coll. of Ohio, Toledo, OH, USA). *Health Phys. (GB)*, vol.44, no.5, p.554-5 (May 1983). The greatest exposure to radiation therapy personnel occurs during brachytherapy procedures. The authors have designed and constructed a shielded loading device which significantly reduces the exposure to the hands and forearms. The device is intended to be used with the Nuclear Associates improved Fletcher-Suit-Delchos applicator system (model 67-980). (no refs.)

78362 Protection in industrial radioscopes in the radiographic examination of objects in nonstationary conditions. L.V.Vladimirov, E.A.Gusev, B.I.Leonov (Sci.-Res. Inst. of Introsocopy, Moscow, USSR). *Sov. J. Nondestr. Test. (USA)*, vol.18, no.9, p.678-81 (Sept. 1982). Translation of: *Defektoskopiya (USSR)*, vol.18, no.9, p.15-19 (Sept. 1982). The principles of the rational construction of biological protection of radioscopes used in nonstationary conditions in industrial production are examined. Models of technical realization of shielding for typical problems of nondestructive inspection are given. (12 refs.)

78363 Radioactive contamination of filamentous green algae in the Hungarian reach of the River Danube. E.Holland, B.Sztanyik, L.Vanicsek ('Frederic Joliot-Curie' Nat. Res. Inst. for Radiobiology & Radiohygiene, Budapest, Hungary). *Acta Phys. Acad. Sci. Hung. (Hungary)*, vol.52, no.3-4, p.419-23 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981). In connection with the national nuclear power station programme a series of measurements was initiated to detect radionuclides in the River Danube. Examinations started in Spring 1978 at six sampling points along the Hungarian reach of the Danube. From among algae of various species of the Danube the localized and well-propagating filamentous green algae (*Cladophora* sp., *Vaucheria* sp.) were investigated. The activity concentration of gamma-radiating nuclides absorbed by algae was determined with a Canberra 8100 type Ge(Li)-spectrometer. This apparatus facilitated radioactivity measurements on wet samples or samples subjected to simple physical preparation. The metabolic character and accumulative abilities of filamentous green algae showed them to be suitable indicators of radionuclide contamination of the water ecosystem. Results are ^{131}I nuclide at min. 72.5 mBq/g to max, 5440.0 mBq/g and other fission products from 55 mBq/g to 929 mBq/g . (7 refs.)

78364 Radioactivity of fish in the Hungarian reach of the River Danube. E.Kurtacs ('Frederic Joliot-Curie' Nat. Res. Inst. for Radiobiology & Radiohygiene, Budapest, Hungary). *Acta Phys. Acad. Sci. Hung. (Hungary)*, vol.52, no.3-4, p.425-7 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981). In connection with the national nuclear power programme a series of measurements was initiated to detect radionuclides in fish of the Danube

river. Since spring 1978 a number of species of fish have been investigated at two sampling points near the nuclear station region. The beta activity of samples was counted with anticoincidence shielded low background Tesla NZ-602 type apparatus. The radioactivity of samples was measured after simple physical or radiochemical preparation. The results show no significant difference according either to sampling place or season. Activity concentrations of ^{90}Sr and ^{137}Cs of natural or global fallout origin are low and hardly differ from values obtained earlier by other researchers. (2 refs.)

78365 Analysis of tritium in tree rings. K.Kozak (Inst. of Isotopes, Budapest, Hungary).

Acta Phys. Acad. Sci. Hung. (Hungary), vol.52, no.3-4, p.429-34 (1982). [received: May 1983] (Proceedings of the Hungarian-Austrian Health Physicists' Meeting, Gyor, Hungary, 28 Sept.-1 Oct. 1981).

Tritium in the cellulose content of the growth rings of two trees was analysed. The two trees were separated by a distance of 5 km; one of them grew just beside the building of the Institute of Isotopes, Budapest. The distribution of tritium concentration in the sequence of the rings of the latter tree showed good agreement with the environmental background concentrations for the years 1957-63. Excess tritium was found in the rings of subsequent years. This was due to the activity of the Institute and indicated the elevated level of the local environment. The tritium content of a few rings of the other tree reflected the environmental background level of the past years and showed no contamination due to the Institute. (8 refs.)

78366 Retention and dosimetry of ^{106}Ru inhaled along with inert particles by Fischer-344 rats. M.B.Snipes, G.M.Kanapilly (Inhalation Toxicology Res. Inst., Lovelace Biomedical & Environmental Res. Inst., Albuquerque, NM, USA).

Health Phys. (GB), vol.44, no.4, p.335-48 (April 1983).

This study was done to provide data useful for predicting the deposition, retention and radiation dose patterns for humans who might be exposed to an aerosol containing $^{106}\text{RuO}_4$ and respirable particles. Ruthenium-106 tetroxide was introduced into air containing inert particles. In addition to condensation of $^{106}\text{RuO}_4$ on pre-existing particles, self-nucleation occurred, presumably resulting from the formation of RuO_3 . It appears there was a significant amount of $^{106}\text{RuO}_4$ present in the inhalation exposure system. When a group of Fischer-344 rats inhaled this exposure atmosphere, approx. 12% of the initial body burden reached the pulmonary region of the respiratory tract. The distribution of the remaining 88% of the initial burden is described. Relative radiation doses accumulated to 100 days after inhalation exposure, normalized to a lung dose of 1.0 are given. Comparable results are predicted for man inhaling a similar exposure atmosphere, which could be encountered under certain circumstances in nuclear industry operations. (22 refs.)

78367 Deposition and retention of ^{141}Ce and ^{134}Cs aerosols on cool desert vegetation. G.C.Millard, L.Fraley, Jr. (Dept. of Radiology & Radiation Biology, Colorado State Univ., Fort Collins, CO, USA), O.D.Markham.

Health Phys. (GB), vol.44, no.4, p.349-57 (April 1983).

Deposition velocities and retention times were obtained for submicron aerosols of ^{141}Ce and ^{134}Cs deposited on two cool desert plant species, big sagebrush (*Artemisia tridentata*) and bottlebrush grass (*Sitanion hystrix*). Mean deposition velocities for sagebrush were 0.18 cm/s (^{141}Ce) and 0.13 cm/s (^{134}Cs). Mean deposition velocities for grass were 0.022 (^{141}Ce) and 0.023 cm/s (^{134}Cs). Species differences were significant ($p < 0.05$), however, nuclide differences were not significant. The loss of activity on the vegetation consisted of two components. A rapid initial loss was found with effective half-times of approx. 1 d (1-8 d for ^{141}Ce and 0.6 d for ^{134}Cs) on sagebrush and approx. 2 d (2.8 d for ^{141}Ce and 2.3 d for ^{134}Cs) on grass. This was followed by a slower, long-term loss with effective half-times ranging from 11 d for ^{141}Ce and 15 d for ^{134}Cs on sagebrush to 9 d for ^{141}Ce and 11 d for ^{134}Cs on grass. (17 refs.)

78368 Effects of recent neptunium studies on high-level waste hazard assessments. B.L.Cohen (Dept. of Phys. & Astron., Univ. of Pittsburgh, Pittsburgh, PA, USA).

Health Phys. (GB), vol.44, no.5, p.567-9 (May 1983).

It has recently been pointed out that alterations in metabolic data given in ICRP Publication 30 (1979) have brought about large changes in hazard assessments of radioactive waste (see B.L. Cohen, *ibid.*, vol.42, p.133, 1982). The most important of these alterations was for ^{237}Np , causing that radionuclide to dominate the long term hazard. The author points out that new studies of neptunium metabolism (see M.F. Sullivan et al., *Radiation Res.*, vol.94, no.1, p.199, 1983; R.C. Thompson, *Radiation Res.*, vol.90, no.1, p.1, 1982) have produced information that largely reverses that alteration, greatly reducing the importance of neptunium in hazard assessment and thereby substantially reducing the total long term hazard. (7 refs.)

78369 The effects of some recording variables on the visual evoked response. I. A comparison of surface and needle electrode recording of the visual evoked response. C.Yiannikas, J.C.Walsh (Dept. of Clinical Neurophysiology, Royal Prince Alfred Hospital, Camperdown, Sydney, Australia).

Am. J. EEG Technol. (USA), vol.23, no.1, p.3-7 (March 1983).

Stainless steel needle and silver/silver chloride surface electrodes are compared with respect to their recording fidelity for visual evoked response. Stainless steel electrodes behave as biological capacitors and at low frequencies have a high impedance and greater electrode offset potential. In the frequency range of the major components of the VER obtained using an amplification system with a high input impedance there is no significant difference in the recordings obtained from the two electrode types. Furthermore, the speed and efficiency of application of subdermal needle electrodes establishes a place for their use in routine evoked potential recording. (13 refs.)

78370 The effects of some recording variables on the visual evoked response. II. The effects of system bandpass on the recording of the visual evoked response. C.Yiannikas, J.C.Walsh (Dept. of Clinical Neurophysiology, Royal Prince Alfred Hospital, Camperdown, Sydney, Australia).

Am. J. EEG Technol. (USA), vol.23, no.1, p.9-14 (March 1983).

For pt.1 see *ibid.*, vol.23, no.1, p.3-7, 1983. The effect of five filter conditions with cutoff ranging from 3.2 kHz to 80 Hz with a 12 db/octave rolloff were studied when averaging the pattern generated visual evoked response. Distortions of the P100 latencies were observed for lowpass filtering below 320 Hz. It is emphasized that the system bandpass should extend at least to 320 Hz when studying the VER components and when estimating the peak latency of the P100 component. Precise information about the system bandpass, including the rolloff and averager sampling rate, should be included in published reports. (8 refs.)

78371 Visual evoked potentials in the newborn: awake and asleep. A.DeGuire, D.G.Glaze, J.D.Frost, Jr. (Dept. of Neurology, Baylor Coll. of Medicine, Houston, TX, USA).

Am. J. EEG Technol. (USA), vol.23, no.1, p.15-23 (March 1983).

Describes the technique of recording the visual evoked potential (VEP) in the newborn during a study conducted to determine the influence of awake-sleep status on evoked potential parameters. It has been established in adults that the VEP waveform characteristics are dependent on the behavioral state, but only limited data have been presented for the infant. The study showed that there is no significant difference between the flash VEP waveforms during waking and sleep in the neonate. It is suggested that the test be performed during sleep so as to minimize artifacts and patient distress. (16 refs.)

78372 Initial results of noninvasive measurement of finger blood pressure according to Penaz. P.G.Molhoek (Dept. of Cardiology, Leiden Univ. Hospital, Leiden, Netherlands), K.H.Wesseling, A.C.Arntzenius, J.J.M.Settels, E.Van Vollenhoven, H.W.H.Weeda, B.De Wit.

Automedica (GB), vol.4, no.4, p.241-6 (1983).

Comparison of simultaneous measurements of intra-arterial pressure in the brachial artery and finger blood pressures (measured noninvasively according to the technique of J. Penaz, see Digest 10th Int. Conf. Med. Biol. Engng., Dresden, p.104, 1973) was performed in 33 patients suspected of having hypertension. In 12 patients evaluation of the technique could not be carried out due to technical failures or highly distorted blood pressure wave forms. Results of the remaining 21 patients showed underestimation of intra-arterial blood pressure by finger cuff blood pressure of 0.8 kPa regarding mean values both for systolic and diastolic measurement, with scatter ranges from 1.9 to -3.5 kPa for systolic, and 0.1 to -2.5 kPa for diastolic values. (6 refs.)

78373 Precordial electrocardiographic map using the IBM-Bonner program. O.Nakagaki, Y.Nose, H.Yano, M.Nakamura (Cardiovascular Clinic, Kyushu Univ. Hospital, Fukuoka, Japan).

Comput. Programs Biomed. (Netherlands), vol.16, no.1-2, p.91-5 (Feb.-April 1983).

The precordial electrocardiographic map may be useful for noninvasive assessment of the extent of the acutely infarcted myocardium. Rapid and serial precordial electrocardiographic maps also may be useful to evaluate the effects of interventions of drugs and efforts on the ischemic myocardium. In this study, the IBM-Bonner program was applied to produce a system for the precordial electrocardiographic map. Six electrodes at one intercostal space were moved in parallel from the second to the seventh intercostal space. Twelve electrocardiograms (ECGs) could be recorded from 36 precordial sites, 6x6 matrix, and analyzed using the IBM-Bonner program. The measured values of the ECG waveform make feasible the automatic procurement of the precordial electrocardiographic map. The authors' mapping program can be used readily and anywhere the IBM-Bonner program is in use. (15 refs.)

78374 The mapping of the measured cardiac electric potential and magnetic-field distribution. M.J.Peters, Z.Dunajski, A.Heringa, R.T.van Dam (Dept. of Tech. Phys., Twente Univ. of Technol., Enschede, Netherlands).

Nuovo Cimento D (Italy), vol.2D, ser.1, no.2, p.311-23 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).

The distribution of both the cardiac electric potential on the body surface and the cardiac magnetic field near the chest and back was recorded at fixed time instants of the heart cycle. The general features of both types of maps are simple and reproducible, moreover they both reveal different information. (9 refs.)

78375 Interference electromyogram processing. I. Influence of the motor unit action potential shape on the interference electromyogram spectra. J.L.Coatrieux (Lab. de Traitement du Signal, Univ. de Rennes I, Rennes, France).

Electromyography & Clin. Neurophysiol. (Belgium), vol.23, no.3, p.229-42 (March-April 1983).

Reports a study on the influence of the motor unit action potential (MUAP) morphology on the electromyogram (EMG) by means of a simulation model and spectral analysis. This work applies to surface and needle EMG signals and suggests signal processing and data analysis methods to discriminate between different pathologies. The author shows: (1) The relation between the interference EMG spectra and the single MUAP mean spectra in the high frequency domain. (2) The influence of higher and lower amplitude MUAPs and linked potentials spectra. (3) The evolution of spectrum shape applied to interference EMG involving a heterogeneous MU population, both diseased and healthy. The analysis is limited to the moderate and unfatigued case where the steady discharge of motoneurons do not show any dependence between intervals of successive nerve impulses. (13 refs.)

78376 Automated analysis of abnormal electroencephalograms. P.Y.Ktonas (Dept. of Electrical Engng., Univ. of Houston, Houston, TX, USA).

CRC Crit. Rev. Biomed. Eng. (USA), vol.9, no.1, p.39-97 (1983).

Presents a critical review of various attempts at computerized analysis of abnormal electroencephalograms (EEGs). A description of normal and abnormal EEGs from the viewpoint of the clinician is presented, along with guidelines used in the visual detection and quantification of EEG abnormalities. A brief review of some important computerized methodologies for clinical EEG analysis is given. Automated detection and quantification of epileptogenic EEG transients and seizures are reviewed, and digital computer (software) as well as hardwired systems are presented. Computerized techniques for the quantification of abnormal EEGs in cerebrovascular disorders and coma, metabolic disorders, and for the localization of brain lesions and tumors are presented. Future directions and the general problem of man-machine agreement are elaborated upon. (169 refs.)

78377 Effects of digital filtering on the waveform and peak parameters of the auditory brainstem response. J.R.Boston (Dept. of Anesthesiology/CCM, School of Medicine, Univ. of Pittsburgh, Pittsburgh, PA, USA).

J. Clin. Eng. (USA), vol.8, no.1, p.79-84 (Jan.-March 1983).

Since the auditory brainstem response (ABR) has a narrower bandwidth than the spontaneous EEG, filtering can be used to improve the signal-to-noise ratio (SNR) prior to averaging. The author compared the effects of different

digital filters. Filters evaluated included lowpass (40-1600 Hz), bandpass (200-1600 Hz), and time invariant a posteriori Wiener filters. All filters were digitally implemented and had zero phase-shift. The filters were digitally implemented and had zero phase-shift. The filters were applied to averaged auditory brainstem responses based on different numbers of individual responses (128 to 1024). The effects of the filters on both room-mean-square (RMS) error and on Jewett wave parameters (peak latency and amplitude) were considered. The lowpass filter did not affect the RMS error or wave amplitude; it did reduce the wave latency variability, but it did not affect the mean latency value. It greatly facilitated wave identification by removing high frequency noise. The bandpass filter behaved similarly, except that a slow wave activity in the response was removed also, resulting in an increased RMS error. The performance of the Wiener filters was essentially the same as the lowpass filters except for a tendency to attenuate the waveform mean square error and wave latency and amplitude variability should be considered. (18 refs.)

78378 Portable processing thermometer. G.Mallet (Lab. de Biophys., Univ. de Nice, Nice, France), D.Maillard.
J. Biophys. & Med. Nucl. (France), vol.7, no.1, p.37-41 (1983). In French. Describes a portable and autonomous instrument allowing on one hand to measure and record, in less than 1 minute, the temperature of 32 samples, and on the other hand, to follow during more than 24 hours tiny temperature variations, with a precision as good as 0.01°C. The recorded data can be transferred to a punch-tape for computer processing. (2 refs.)

78379 Contribution of measurement system artifacts to systolic spikes. Z.Ladin, E.Trautman, R.Teplick.
Med. Instrum. (USA), vol.17, no.2, p.110-12 (March-April 1983). A clinical study was conducted to determine if the systolic spike often observed in an invasive blood pressure display originates in the measurement system. The clinical system consisted of a catheter, stopcocks, 4 ft of tubing, an amplifier (containing a 12-Hz low-pass filter), and a continuous flush device. A second transducer was connected directly to the patient's catheter, in parallel with the clinical system. Its output was conditioned by an amplifier modified to exclude the low-pass filter. Simultaneous measurements were taken from both transducers, recorded, and later analyzed. A comparison of the traces in the time domain, as well as an analysis of the signals in the frequency domain, suggests that the systolic spike did not originate in the pressure tubing or in the amplifier system. (6 refs.)

78380 A simple means for recording foot contact sequence during gait. G.F.Harris, R.E.Halbach.
Med. Instrum. (USA), vol.17, no.2, p.119-20 (March-April 1983). A simple circuit has been developed that can be used in conjunction with standard gait analysis foot switches to decrease the number of channels needed for recording. (3 refs.)

78381 A microprocessor-based arrhythmia monitor/recorder for the operating and recovery rooms. A.V.Sahakian, W.J.Tompkins, B.M.Tompkins, J.F.Kreul.
Med. Instrum. (USA), vol.17, no.2, p.131-4 (March-April 1983). A microprocessor-based cardiac arrhythmia monitor/recorder was designed to detect and document arrhythmias that occur during general anesthesia. A Holter tape recorder controlled by the monitor records arrhythmias and associated annotation. These condensed records are later manually scanned for final classification. The project was undertaken to build a database of arrhythmias correlated with various inhalation anesthetic agents, while simultaneously evaluating real-time rhythm analysis algorithms. (6 refs.)

78382 Breast tissue classification using diagnostic ultrasound and pattern recognition techniques. I. Methods of pattern recognition. S.Finette, A.Bleier, W.Swindell (Dept. of Radiology, Univ. of Arizona, Tucson, AZ, USA).
Ultrasound Imaging (USA), vol.5, no.1, p.55-70 (Jan. 1983). Discusses the application of statistical pattern recognition techniques to problems in diagnostic ultrasound. Using their own system as an example, the authors describe the concepts and specific methods that they have applied to a problem involving the computer-aided classification of breast tissue in vivo. Topics include feature generation, feature selection and classification, as well as a method which estimates the probability of error on classifying future data. (27 refs.)

78383 Breast tissue classification using diagnostic ultrasound and pattern recognition techniques. II. Experimental results. S.Finette, A.R.Bleier, W.Swindell, K.Haber (Univ. of Arizona, Tucson, AZ, USA).
Ultrasound Imaging (USA), vol.5, no.1, p.71-86 (Jan. 1983). For pt.1 see ibid., vol.5, no.1, p.55 (1983). The methods of statistical pattern recognition have been applied to the problem of in vivo ultrasonic characterization of breast disease in humans. Backscattered A-mode signals obtained from a commercial pulse imaging system were used to generate a large set of potentially useful features. Using statistical tests, a small subset of discriminatory features was selected to design a Bayes decision rule for each of two tissue classification schemes: malignant disease vs. benign disease, and malignant disease vs. (benign disease+normal tissue). Classification results obtained by the rotation method included sensitivities of 88 percent and 76 percent for the two schemes, based on data obtained from 32 women. These results are encouraging, though a definitive statement concerning the extrap-

olation of these numbers to the general population should only be made after obtaining results with a large data base. (26 refs.)

78384 Image restoration in CT by the method of projection onto convex sets. M.I.Sezan, H.Stark (Dept. of Electrical, Computer & Systems Engng., Rensselaer Polytech. Inst., Troy, NY, USA).
Proceedings of ICASSP 83. IEEE International Conference on Acoustics, Speech and Signal Processing, Boston, MA, USA, 14-16 April 1983 (New York, USA: IEEE 1983), p.139-42 vol.1

In many foreseeable applications of computerized tomography (CT) it may not be possible (e.g., because of obstructions) to obtain 360 degree view-data and reconstruction from partial view data may be unsatisfactory. In this paper the authors describe the method of projections onto convex sets (POCS) by which the missing data can be restored from partial viewdata and a priori known properties of the original image. POCS performs significantly better than the conventional Gerchberg-Papoulis (GP) method. (10 refs.)

87.70J Prosthetics and other practical applications

- 78385 Visual perception of a phonemic code for a tactile hearing aid.** Hoi-Young Chan, E.M.O'Brien (Clemson Univ., Clemson, SC, USA). IEEE SOUTHEASTCON '83 Conference Proceedings, Orlando, FL, USA, 11-14 April 1983 (New York, USA: IEEE 1983), p.376-9.
 A new type of tactile hearing aid is considered which will present only phonemic information to the tactile senses of totally deaf people. This will relay on a speed-to-phoneme convertor which is still not a reality but will be someday. A phonemic code has been evaluated visually. The code consists of a 2x4 array of on-off stimulators to represent the 41 phonemes of English. Single phonemes through five phoneme words were evaluated by seven subjects. The percent correctly perceived were as follows: single phonemes, 98%; two phoneme through five phoneme words, 90, 82, 78 and 74% respectively. The phonemes were presented at a rate of about one per second which is well below normal speed for spoken English. However, the results are encouraging given the brief exposure of the subjects to the code. The next step is a tactile evaluation of the code. (3 refs.)

87.80 BIOPHYSICAL INSTRUMENTATION AND TECHNIQUES

- 78386 Inhalation chambers for air ion research.** J.M.Charry, P.A.Cerniglia, J.M.Weiss (Rockefeller Univ., New York, NY, USA), T.J.Michel, R.F.Finger. *Bioelectromagnetics (USA)*, vol.4, no.2, p.167-80 (1983).
 Many previous problems in establishing the nature of biological and behavioural effects of small air ions have been due to poor control over the ion-inhalation and microclimate, resulting in nonuniform electrical fields and highly uneven concentrations of small air ions. The authors have developed a corona discharge air ion-inhalation system for use with animals that incorporates rigorous control over the microclimate and produces highly uniform concentrations of small air ions throughout the exposure area. (15 refs.)
- 78387 Application of interferometry to the monitoring of sheep and cattle behaviour in arid zone paddocks.** B.R.Davis (Dept. of Electrical Engng., Univ. of Adelaide, Adelaide, S Australia), M.C.Willcocks. *Bioelectm. & Patient Monit. (Switzerland)*, vol.9, no.4, p.185-204 (1982).
 Reviews methods of monitoring animal movement and behaviour in response to environmental changes. The method based on radio interferometry is discussed in some detail, including consideration of the criteria which determine the choice of system parameters such as operating frequency and transmitter power. A prototype system based on radio interferometry and applied to the study of sheep behaviour in arid zones is described and some preliminary results presented. Suggestions for improvement and realization as a full automated data acquisition system are included. (23 refs.)
- 78388 An implantable, externally powered radiotelemetric system for long-term ECG and heart-rate monitoring.** B.Hansen (Finsen Lab., Copenhagen, Denmark), K.Aabo, J.Bojsen. *Bioelectm. & Patient Monit. (Switzerland)*, vol.9, no.4, p.227-37 (1982).
 An externally inductive powered implantable ECG radiotelemetry unit has been developed for continuous long-term measurements of cardiophysiological changes following administration of cardiotoxic drugs. The power density distribution (320 kHz) inside the cage has been measured to be 3-11 mW/cm². The implantable unit has a volume of 38x22x8 mm and a mass of 9 g, and has been tolerated by the animal (guinea pig) during a continuous registration period of 6 months. (7 refs.)
- 78389 On-line analysis of neuromuscular bioelectric potentials.** S.R.Quint (Dept. of Neurology, Univ. of North Carolina School of Medicine, Chapel Hill, NC, USA), J.F.Howard, Jr., L.Antoni. *Comput. Programs Biomed. (Netherlands)*, vol.16, no.1-2, p.3-12 (Feb.-April 1983).
 A computer system is presented which provides for on-line data capture and analysis of evoked end-plate potentials and action potentials, and on-line data capture with off-line analysis of spontaneously occurring miniature end-plate potentials at the end-plate region of the neuromuscular junction. Sampling of evoked waveforms begins after an adjustable delay following the stimulus. Spontaneously occurring waveforms are captured by 'freezing' the contents of a circular buffer. The software provides MENU selectable support functions including storage and retrieval of data and calculated parameters, analog and digital display of waveforms, data calibration and gain modification, data editing, file management, and hardcopy output. Calculated parameters of the waveform are optionally placed in a data base file by the analysis programs. The data base may be used for editing, arithmetic operations, and subsetting of variables as well as statistical analysis and plotting of any selected variables. (14 refs.)
- 78390 A fast method for arranging DNA sequence fragments.** G.Osterburg, K.H.Glatting, J.Buchert (German Cancer Res. Center, Inst. of Documentation, Information & Statistics, Heidelberg, Germany), J.Wolters. *Comput. Programs Biomed. (Netherlands)*, vol.16, no.1-2, p.61-9 (Feb.-April 1983).
 A method is described which allows efficient arrangement of DNA sequence fragments and, based on this arrangement, reconstruction of a complete DNA sequence. The concepts and algorithms used are based on the mathematical theory of graphs. The amount of human interaction required is considerably reduced compared to existing methods. An experiment with a set of 168 fragments yields a DNA sequence of about 5800 bases almost automatically. (4 refs.)
- 78391 Mechanical model of the insect eye.** R.T.Schneider (Dept. of Nuclear Engng. Sci., Univ. of Florida, Gainesville, FL, USA), J.F.Long. *Proc. SPIE Int. Soc. Opt. Eng. (USA)*, vol.359, p.139-49 (1983). (Applications of Digital Image Processing IV, San Diego, CA, USA, 24-27 Aug. 1982).
 Most optical instruments in use are modeled after the human eye. The design of insect eyes is fundamentally different and is governed by the laws of multiaperture optics. It can be shown that for certain applications, instruments using multiaperture optics are superior to single aperture instruments. For study of multiaperture optics and function of the insect eye a mechanical model resembling an insect eye was constructed. An individual eyelet of the

- mechanical model consists of a lens system and a detection system. The diameter of the front lens is 2 mm (7 mm f1), the aperture of the back lens is 1 mm (2 mm f1). Each eyelet has seven optical fibers which transport the incident light to individual detectors. The model has a total of 100 eyelets (700 detectors). Each detector is sequentially read by a multiplexer which is interfaced with a microcomputer, which displays the output on a video terminal. (10 refs.)
- 78392 Processing of noisy high resolution electron micrographs of crystalline biological membranes.** S.B.Luscher (Inst. für Kommunikationstechn., Zurich, Switzerland). *Proc. SPIE Int. Soc. Opt. Eng. (USA)*, vol.359, p.233-41 (1983). (Applications of Digital Image Processing IV, San Diego, CA, USA, 24-27 Aug. 1982).
 The problems associated with the interpretation of structure preserving low-dose electron micrographs have been solved for crystalline biological specimens by using specialized image processing routines. Fourier domain techniques are used to extract the periodic signal component. Hardly visible in the noisy unprocessed micrograph, the periodic structure becomes manifest by the discrete reflexions in the power spectrum. The different filtering methods and symmetrisation procedures have been applied to noisy, low contrast electron micrographs of crystalline sheets of various biological specimens. The increase in interpretability and reliability of structure determination is demonstrated at the different stages of processing. (7 refs.)
- 78393 Instrumentation for biomagnetism.** D.Duret (LETI, CEA, Grenoble, France), P.Karp. *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.123-41 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).
 The instrumentation suitable for the acquisition of biomagnetic signals is reviewed. The basic magnetometer components, i.e. SQUIDs, flux transformers and dewars, are studied separately. Possible improvements to the present instrumentation as well as complete set-ups including ferromagnetic or eddy current shields are discussed and their efficiency evaluated. (57 refs.)
- 78394 First-gradient balancing of higher-order gradiometers [biomagnetism application].** J.Vrba, J.McCubbin (CTF Systems Inc., Port Coquitlam, BC, Canada). *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.142-52 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).
 A formalism for the vector and tensor description of a balancing procedure is developed and a first-gradient and field-balancing method is outlined. The experimental apparatus and measurements of the first-gradient common-mode vector, C_{G1} , are discussed. (11 refs.)
- 78395 Measurement of biomagnetic fields using multichannel superconducting-magnetometer techniques.** M.Seppanen, T.Katila, T.Tuomisto, T.Varpula (Dept. of Tech. Phys., Helsinki Univ. of Technol., Espoo, Finland), D.Duret, P.Karp. *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.166-74 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).
 The authors have constructed a three-channel differential SQUID magnetometer for the simultaneous measurement of the three orthogonal components of the magnetic field in the same location. The structure of the device is described and MCG data measured are shown. Interference effects between the channels are discussed. (10 refs.)
- 78396 An eddy-current-shielded room with a partially closed entrance [for biomagnetic measurements].** G.Stroink, C.Purcell, F.Brauer, B.Blackford (Dept. of Phys., Dalhousie Univ., Halifax, NS, Canada). *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.195-202 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).
 It is shown that substantial improvements can be obtained in the shielding properties of an eddy-current-shielded room by covering the doorway with conductive plates. Results suggest that it is unnecessary to install a conductive door and show that it is worthwhile covering a small part of the doorway permanently. (6 refs.)
- 78397 Adaptive noise cancellation in neuromagnetic measurement systems.** J.S.Hansen, D.Bowser, H.Ko (Appl. Phys. Lab., Johns Hopkins Univ., Laurel, MD, USA), D.Brenner, F.Richer, J.Beatty. *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.203-13 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).
 The noise spectrum of a superconducting second-derivative gradiometer has been investigated in an urban environment. Data have been acquired from the gradiometer with three orthogonal accelerometers and a triaxial fluxgate magnetometer attached to the dewar. These data have been analysed by using signal processing techniques, primarily an adaptive noise canceller, to reduce noise in the gradiometer data. Results shown here indicate that the environmental noise and/or the dewar motion noise can be reduced as much as 40 dB in noise power. It is also shown, in the case of poor signal-to-noise ratio ($S/N \sim 1$), that a 10 Hz sine wave can be extracted. This technique not only shows promise for noise reduction, but also aids in the identification of noise signals which might be misconstrued as part of the evoked response. Analysis of data containing evoked responses is now underway. (4 refs.)
- 78398 Alternatives to the SQUID magnetometer for some biomagnetic measurements.** Z.Trontelj, J.Luznik, J.Pirnart (Dept. of Phys., Univ. E. Kardeelj of Ljubljana, Ljubljana, Yugoslavia). *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.214-23 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).
 Flux gate and resonance type of magnetometers (free precession, optically pumped), which can in some cases replace the SQUID magnetometer, are discussed. The principles of operation, sensitivity, dynamical range and frequency response are described. The application of these magnetometers for biomagnetic measurements is mentioned. (19 refs.)
- 78399 A portable biomagnetic measuring system.** V.L.Vvedensky, S.P.Naurzakov, V.I.Ozhogin, S.Yu.Shabanov (Kurchatov Inst. of Atomic Energy, Moscow, USSR). *Nuovo Cimento D (Italy)*, vol.2D, ser.1, no.2, p.224-30 (March-April 1983). (Proceedings of the Fourth International Workshop on Biomagnetism, Rome, Italy, 14-16 Sept. 1982).
 The instrumentation for biomagnetic applications is described. The small size and weight of the SQUID gradiometer permit easy transport and positioning of the instrument, thus making biomagnetic measurements possible in any noise-free location. The equipment is provided with a battery power supply, and, when filled with 60 cm³ of liquid helium, will operate continuously for 6 h. The device is suitable for magnetocardiography. (3 refs.)

78400 The use of time domain dielectric spectroscopy to characterize the progress of wound repair. F.X.Hart (Dept. of Phys., Univ. of the South, Sewanee, TN, USA). *J. Bioelectr. (USA)*, vol.1, no.3, p.313-28 (1982).
The electrical properties of wounded plant tissue are observed to change during the course of healing. Such changes could serve as an objective measure of the progress of repair. Time domain dielectric spectroscopy is used to rapidly measure these properties. Under microprocessor control a voltage step is applied to a stem and the resulting current-time characteristic sampled. Fourier Transformation yields the variation of stem conductance and capacitance with frequency. (5 refs.)

78401 Peak-shape analysis for protein neutron crystallography with position-sensitive detectors. B.P.Schoenborn (Biology Dept., Brookhaven Nat. Lab., Upton, Long Island, NY, USA). *Acta Crystallogr. Sect. A (Denmark)*, vol.A39, pt.3, p.315-21 (1 May 1983).
In neutron protein crystallography, the use of position-sensitive detectors controlled by a modern data acquisition system permits new approaches to data collection strategies. Instead of dealing with conventional scans, like the θ - 2θ scan, that provide an integrated intensity as a function of a rotational parameter, the computer-linked counter can be used to produce a three-dimensional reflection profile. As the crystal steps ($\Delta\omega$) through a reflection, the observed data for each step are stored in an external memory as a function of extent in 2θ and height (y) of a reflection. In this space, the reflection will be a three-dimensional distribution with dimensions determined by such basic geometrical conditions as $\Delta\lambda$, crystal size, mosaic spread, counter-resolution, and beam-collimation parameters. Knowledge of the interaction of these basic parameters will allow the design of optimal beam optics and will permit the delineation of the reflection from the background and permit, therefore, an accurate intensity determination. (21 refs.)

78402 Characterization of the solid components of biological tissues by cross-polarization, magic angle NMR spectrometry. C.E.Brown (Dept. of Biochem., Medical Coll. of Wisconsin, Milwaukee, WI, USA), C.A.Wilkie. *CRC Crit. Rev. Biomed. Eng. (USA)*, vol.9, no.1, p.1-38 (1983).
A biological tissue is composed of cytosol, which can be investigated by high resolution nuclear magnetic resonance (NMR) spectroscopy, and membrane and particulate components, which yield NMR spectra similar to those of solids. In this review, the theoretical and technical requirements of recording NMR spectra of solids with cross polarization and magic angle sample spinning techniques are compared with the physical characteristics of the solid components of biological tissues. Current applications of cross-polarization, magic angle NMR spectroscopy to the investigation of membranes, mineral deposits and biosynthetic pathways are presented and discussed in terms of the biomedical questions to which this technique might be applied. (277 refs.)

78403 Multichannel microelectrode for recording neural activity. J.J.Cuomo, W.W.Molzen, J.L.Speidel (IBM Corp., Armonk, NY, USA). *IBM Tech. Disclosure Bull. (USA)*, vol.25, no.11A, p.5588-97 (April 1983).
Relates generally to apparatus for recording electrophysiological data and more particularly to a multichannel microelectrode for recording neural activity. The microelectrode contains an array of recording sites connected via transmission lines to output pad circuits. (no refs.)

78404 Combining accurate defocus with low-dose imaging in high resolution electron microscopy of biological material. N.G.Wrigley, E.Brown, R.K.Chillingworth (Nat. Inst. for Medical Res., London, England). *J. Microsc. (GB)*, vol.130, pt.2, p.225-32 (May 1983). (MICRO 82: High Resolution Electron Microscopy, London, England, 12-16 July 1982).
High resolution (<2 nm) electron microscopy of biological specimens requires three exacting conditions to be met simultaneously: (a) fine specimen detail must be protected from destruction by the electron beam (low dose), (b) the electron optics must be adjusted to be capable of imaging that detail interpretably (accurate defocus), and (c) a suitable field of interest must be identified. The authors describe a method encompassing all three with an 80% success rate using only minor modifications to a transmission electron microscope, and no expensive on-line computing. (17 refs.)

78405 Determination of radium-226 in urine. G.H.Kramer, P.C.Beaulieu. *Report AECL-7979*, Atomic Energy Canada Ltd., Chalk River, Ont. (March 1983), 14 pp.
The method for determining radium-226 in urine that is currently being used by the Bioassay Laboratory has been tested and documented. Radium-226 is coprecipitated from urine by alkaline calcium phosphate. This precipitate is redissolved in hydrochloric acid and the radium purified by cation exchange. Radium is collected by a barium sulphate coprecipitation and then estimated by alpha counting. The method has been tested using radium-226 and cross-contamination studies were performed using Am-241, Pu-239, Np-237, Th-Nat and U-233. With the exception of Am-241, cross-contaminations were found to be negligible. The method gives an overall chemical recovery of $80 \pm 5\%$ and the detection limit is estimated to be 0.39 mBq-counting time, 71 h; background, 0.05 counts per minute (cpm). (22 refs.)

78406 Biomedical applications of MWPC's for digital imaging of soft β emitters. R.Bellazzini, A.Del Guerra, M.M.Massai, G.Spandre. *Report INFN/TC-83/6*, Ist. Naz. Fis. Nucl., Pisa, Italy (24 Feb. 1983), 6 pp.
The authors have built an experimental facility equipped with MultiWire Proportional Chambers (MWPC) and a PDP 11/23 mini-computer for the digital imaging of two-dimensional ^3H distributions in biological and medical applications. A spatial resolution of ~ 1.5 mm (FWHM), a sensitivity of 10^{-1} Bq/cm 2 , and an efficiency of $\sim 10\%$ with a uniformity of 4% have been measured with a MWPC working at atmospheric pressure with 2 mm anode pitch and cathode coupled delay line read-out. A second chamber with 1 mm anode pitch at 45° with respect to the cathode wires has been operated at 2 atm. In this case a spatial resolution of ~ 800 μm (FWHM) for ^3H sources has been measured along both directions. The authors present images for the identification of human clones with defective repair of UV-induced damage, and for the study of regional carbohydrate consumption in myocardial tissue. (6 refs.)

78407 Contact microscopy of biological specimens using synchrotron radiation. P.C.Cheng (Dept. of Anatomy, Univ. of Illinois, Medical Center, Chicago, IL, USA), R.J.Howe, J.W.McGowan, D.M.Shinozaki. *Fifteenth Annual Synchrotron Radiation Users Group Conference* (papers in summary form only received), Stoughton, WI, USA, 18-19 Oct. 1982 (Stoughton, WI, USA: Synchrotron Radiat. Center 1982), p.12
Attempts were made to produce contact microscopic images of biological specimens on PMMA X-ray resist with synchrotron radiation. *Xenopus laevis* embryo cells were cultured in Formvar coated (1500 Å) gold grid grids, fixed in 1% glutaraldehyde; dehydrated in ethanol and critical point dried in CO $_2$. The grids are then placed in intimate contact with PMMA (polymethylmethacrylate; 0.6 μm or 2 μm) resist (either supported by a Si $_3$ N $_4$ window or a silicon wafer). Exposures are made on Tantalus either with an Al filter 0-72 eV, below or above the phosphorous edge or with 130 eV (95.4 Å) and 140 eV (88.5 Å) monochromatic light. The exposures with Al filtered light are

15-60 minutes while the exposure with monochromatic light requires approximately 8 hours. Detailed biological structures such as nucleus, nucleolus, stress fiber, yolk granulus, mitochondria can be clearly visible. Microchemical analysis of phosphorus is in progress. (no refs.)

78408 A fiber optics fluorimeter for algae detection and mapping. T.Lund. *First International Conference on Optical Fibre Sensors*, London, England, 26-28 April 1983 (London, England: IEE 1983), p.190-4
Optical fiber bundles provide a very versatile means for in situ fluorescence studies of natural water. The technique is also applicable to other in situ natural targets, like vegetation, and it may further prove useful in a variety of general industrial measurement tasks. The completely passive sensor head can, with proper choice of optical fibers, withstand excessive pressures and temperatures. Furthermore, monitoring of elastic scattering, attenuation and environmental light should require only minor modifications to the sensor head. The fiber bundle approach also allows for use of a number of source/receiver combinations. In particular, use of a low power HeNe laser to monitor blue-green algae, which is of increasing importance in lake eutrophication, seems a promising example. (7 refs.)

87.90 OTHER TOPICS IN BIOPHYSICS, MEDICAL PHYSICS, AND BIOMEDICAL ENGINEERING

78409 Health risks from electricity generation. B.L.Cohen (Univ. of Pittsburgh, Pittsburgh, PA, USA). *Comments Mol. & Cell. Biophys. Comments Mod. Biol. Part A (GB)*, vol.2, no.1, p.1-15 (April 1983).
According to the author's analysis, nuclear electricity has far milder health effects than coal burning or photovoltaic technologies. On a short term basis, the 25 deaths/GWe-yr from coal burning greatly exceeds the 0.12 from nuclear, or even the 2.5 claimed by antinuclear activists. For photovoltaics, the 3% of coal burning predicts 0.8 deaths/GWe-yr, still many times larger than the government estimates for nuclear. On a long term basis, the deaths from both coal and photovoltaics greatly exceed those from nuclear high level waste, not to mention the very large life saving contribution from mining uranium, 3000 times the effects of high level waste. (20 refs.)

90.00 GEOPHYSICS, ASTRONOMY AND ASTROPHYSICS

91.00 SOLID EARTH GEOPHYSICS

78410 Evolution of the Earth-Moon system. B.Czapiewska, M.Bielicki (Obs. Astron., Uniwersytetu Warszawskiego, Warsaw, Poland). *Postępy Astron. (Poland)*, vol.30, no.3-4, p.239-58 (July-Dec. 1982). In Polish. [received: April 1983]
Observations concerning the time-scale of the orbital evolution of the Earth-Moon system are presented. The results obtained with different methods are compared. The most probable value characterizing this evolution—the Moon's acceleration—is $16''/\text{century}^2$, which corresponds to increasing the Moon's distance at 2.3 cm/year. It is shown that the results obtained from archaic corals are reliable. (9 refs.)

91.10 GEODESY AND GRAVITY
(for relations of gravity observations to tectonics and isostasy, see 91.45 Physics of plate tectonics)

78411 A numerical study of the divergence of spherical harmonic series of the gravity and height anomalies at the Earth's surface. C.Jekeli (Air Force Geophys. Lab., Hanscom AFB, Bedford, MA, USA). *Bull. Geod. (France)*, vol.57, no.1, p.10-28 (1983).
The problem of the divergence of the geopotential spherical harmonic series at the Earth's surface is investigated from a numerical, rather than a theoretical, approach. A representative model of the Earth's potential is devised on the basis of a density layer, which, in the spherical approximation, generates a gravity field whose harmonic constituents decay according to an accepted degree variance model. This field, expanded to degree 300, and a topographic surface specified to a corresponding resolution of 67 km are used to compute the differences between truncated inner and outer series of the gravity and height anomalies at the surface of the Earth model. (18 refs.)

78412 Effects of adopting new precession, nutation and equinox corrections on the terrestrial reference frame. S.-Y.Zhu, I.I.Mueller (Dept. of Geodetic Sci. & Surveying, Ohio State Univ., Columbus, OH, USA). *Bull. Geod. (France)*, vol.57, no.1, p.29-42 (1983).
The effect on polar motion is a diurnal periodic term with an amplitude increasing linearly in time; on UT1 it is a linear term. The effects of small rotations (such as precession, nutation or equinox corrections) of the frame of a Conventional Inertial Reference System (CIS) on the frame of the Conventional Terrestrial Reference System (CTS) are given. Seven CTS options are

presented, one of which is necessary to accommodate such rotations (corrections). The last of these options requiring no changes in the origin of terrestrial longitudes and in UT1 is advocated; this option would be maintained by eventually referencing the Greenwich Mean Sidereal Time to a fixed point on the equator, instead of to the mean equinox of data, the current practice. Accommodating possible future changes in the astronomical nutation is discussed. The Appendix deals with the effects of differences which may exist between the various CTSs and CISs (inherent in the various observational techniques) on Earth rotation parameters (ERP) and how these differences can be determined. (10 refs.)

78413 Sparse matrix algorithms applied to DEM generation. W.Stark (Univ. Stuttgart, Stuttgart, Germany), F.Steidler. *Bull. Geod. (France)*, vol.57, no.1, p.43-61 (1983). A method for generating a digital elevation model (DEM) was suggested by Ebner (1979). The heights of grid points are interpolated from arbitrarily distributed reference points using the finite element method. The requested grid heights of the DEM are defined as unknowns and estimated from the available reference points and a general curvature minimization of the interpolation surface with filtering at the reference points. This problem can be interpreted as an adjustment of indirect observations and can be solved using the least squares method. This leads to a banded structured system of normal equations in case of numbering the unknowns in a row-wise order. This ordering may not be the best strategy for the solution of the normal equations, because the band contains many zero elements. Therefore algorithms which exploit the nonzero/zero structure to better advantage have been applied in combination with the pivot strategies of 'Nested Dissection' and 'Minimum Degree Ordering' (OPTORD). The operational characteristics of these algorithms are compared with those of the band-algorithm for several DEM problems that vary in size to over 4000 unknowns. (16 refs.)

78414 Gravity anomalies, seismic structure and geothermal history of the central Alps. E.Kissling, St.Mueller, D.Werner (Inst. fur Geophys., ETH-Honggerberg, Zurich, Switzerland). *Ann. Geophys. (France)*, vol.1, no.1, p.37-46 (Jan.-Feb. 1983). A new interpretation of the gravity anomalies in the Swiss Alps from the geothermal point of view is presented. The regional gravity distribution is partly caused by the topography of the crust-mantle boundary. Taking 0.5 g/cm^3 as the average density contrast between crust and mantle the Bouguer map of Switzerland contains a residual field which indicates a density anomaly in the mantle. This finding, results from seismic surface-wave investigations, and P -wave travel time observations can be interpreted as a consequence of the genesis of the Alps. A kinematic model of the Alps is constructed simulating the mass displacements during the last 40 m.y. In this two-dimensional model the subsidence of cold mantle material is taken into consideration forming a 'lithospheric roof'. Based on this kinematic model the temperature distribution in the moving medium can be calculated, taking into account the radiogenic heat sources. From the calculated temperature field at present time the thermally induced density deviation can be determined. (34 refs.)

78415 Tidal friction in historical time and in the remote past. B.Jeffreys (Girton Coll., Cambridge, England). *Geophys. J. R. Astron. Soc. (GB)*, vol.73, no.3, p.765-8 (June 1983). Comments on Jeffreys's (1982) extension of his treatment of tidal friction in historical time. Amendments are presented of the theory given in *The Earth* (Jeffreys, 1970, 1976) concerning the Moon's orbit and the Earth's rotation in the remote past. (11 refs.)

78416 Stokes's theorem for the case of many isolated bodies. M.A.Aleksidze (Inst. of Geophys., Acad. of Sci., Georgian SSR). *Izv. Acad. Sci. USSR. Phys. Solid Earth (USA)*, vol.18, no.2 (1982). Translation of: *Izv. Akad. Nauk SSSR Fiz. Zemli*, vol.18, no.2, p.111-18 (1982). Examines problems of the determination of the external potential for many isolated bodies when the total masses of the bodies and, with an accuracy up to arbitrary terms, the potential on the closed surfaces, are given rather than the density distribution within the bodies. (9 refs.)

78417 Solution of inverse gravimetric problems for several contact surfaces. V.I.Starostenko, A.N.Zavorot'ko (S.I. Subbotin Inst. of Geophys., Acad. of Sci., Ukrainian SSR). *Izv. Acad. Sci. USSR. Phys. Solid Earth (USA)*, vol.18, no.3, p.196-206 (1982). Translation of: *Izv. Akad. Nauk SSSR Fiz. Zemli*, vol.18, no.3 (1982).

Statements of inverse linear and nonlinear gravimetric problems are given for a number of contact surfaces. In the solution of linear problems, excessive densities of layers situated between known contact surfaces are determined. The solution of nonlinear problems makes it possible to reconstruct the position of several contacts if the layer densities are known, as well as the position of the upper (or lower) contact. Algorithms by Tikhonov (1979) for refining the solution are presented, with particular attention given to the nonlinear case. The efficiency of the methods of solution used are illustrated by examples. (20 refs.)

78418 Direct integration of Stokes' undulation and Vening Meinesz's deflection equations for geographically defined gravity anomaly blocks. G.Obenson (Univ. of Lagos, Lagos, Nigeria). *J. Geophys. Res. (USA)*, vol.88, no.B1, p.665-8 (10 Jan. 1983). [received: May 1983]

Gives a direct solution of this problem by converting, in an indirect way, the relevant integral equations over each block to their equivalent line integrals taken along and around the boundary curves of the block. Results of sample computations given clearly demonstrate the convergence and stability of these line integrals. Geoidal parameters due to a $30^\circ \times 30^\circ$ inner zone alone at 71 grid locations in Cameroon are calculated using $1^\circ \times 1^\circ$ anomalies and integration steps of 30° for the four innermost blocks and 180° for the rest of the blocks and compared these with equivalent values from the midpoint method. (5 refs.)

78419 Global postseismic deformation in a stratified viscoelastic Earth: effects on Chandler wobble excitation. M.Dragoni, D.A.Yuen (Dept. of Geology, Arizona State Univ., Tempe, AZ, USA), E.Boschi. *J. Geophys. Res. (USA)*, vol.88, no.B3, p.2240-50 (10 March 1983). The principle purpose of this paper is to examine whether movement of matter in a stratified viscoelastic Earth can enhance the excitation of the Chandler wobble. A two-layer model consisting of an elastic lithosphere overlying a Maxwell viscoelastic mantle is constructed in order to calculate explicitly the temporal evolution of the inertia tensor from earthquake faulting. It is found that the ability of the viscoelastic flows to produce an additional increment of the inertia tensor depends critically on R , the ratio of the inner radius to the outer radius. Only for $R \geq 0.7$ is there a substantial increase. For the Earth ($R \approx 0.98$) an amplification of between four and six is obtained from the models considered. However, the time scales over which this enhancement of the moment of inertia takes place is about 10 Maxwell times, thus making this model unlikely to excite the Chandler wobble for values of the mantle viscosity derived from postglacial uplifts. (28 refs.)

78420 Tidal gravity parameters at Brussels reconfirmed by a superconducting gravity meter. B.Ducarme (Obs. Royal de Belgique, Brussels, Belgium). *Phys. Earth & Planet. Inter. (Netherlands)*, vol.32, no.1, p.2-3 (April 1983). The results of the Trans World tidal gravity profiles (67 stations established in Asia, South Pacific and East Africa) are based upon instrumental constants determined at Brussels as the fundamental station. A superconducting gravimeter operating at Brussels for only two months fully reconfirms the instrumental constants related to the instrumental phase lags. (6 refs.)

91.25 GEOMAGNETISM AND PALAEOMAGNETISM; GEOELECTRICITY

78421 Existence and interpretation of an electrically conducting zone within the plateau basalts of Kerguelen Islands (TAAF). R.Ballestracci (UER Sci. et Tech., Univ. Toulon, La Garde, France), J.Nougier, Y.Benderitter. *C.R. Seances Acad. Sci. Ser. II (France)*, vol.296, no.11, p.833-8 (21 March 1983). In French.

A reconnaissance field-trip by audiomagnetotelluric profiles has been carried out on Kerguelen Islands (Terres australes et antarctiques francaises) where historic eruptions and hydrothermal post-volcanic phenomena are recorded. Data processing of profiles made over the plateau basalts pillings are specified. They show a conducting level parallel to the topographic surface and located between 500 and 700 m deep with a thickness over 300 m. Critical analysis of this anomaly favors a hydrothermic system of convection type. The upper conducting limit should be the highly ionised interface between downward meteoritic waters and thermic gradients, the temperature being relatively low. The example of hot springs is analysed as characteristic of a system drained by an open fracture and a fast water transit. (14 refs.)

78422 Difference in autocorrelation functions of AA-indices for the northern and southern hemispheres. E.M.Apostolov (Geophys. Inst., Bulgarian Acad. of Sci., Sofia, Bulgaria). *C.R. Acad. Bulg. Sci. (Bulgaria)*, vol.36, no.1, p.77-9 (1983).

The average monthly values of the aa-indices for the series N and S for the 1968-1979 period were used to analyse the degree of dependence between the values of each time series and then to compare them. (1 ref.)

78423 A palaeomagnetic reconnaissance of Kashmir, northwestern Himalaya, India. C.T.Klootwijk (Res. School of Earth Sci., Australian Nat. Univ., Canberra, Australia), S.K.Shah, J.Gergan, M.Lal Sharma, B.Tirkey, B.K.Gupta. *Earth & Planet. Sci. Lett. (Netherlands)*, vol.63, no.2, p.305-24 (May 1983).

Thermal demagnetization studies of 800 Palaeozoic and Lower Mesozoic samples, mainly carbonates, from 14 localities in Kashmir, showed four magnetic components: (A) A recent field component of normal polarity and large intensity. (B) A Middle to Late Tertiary secondary component of large intensity and of reversed and normal polarity, which indicates clockwise tectonic rotation of central and eastern Kashmir. (C) Primary magnetic components of Triassic, Late Permian, Early Carboniferous, Siluro-Ordovician and Middle to Early Ordovician age. The Triassic and Late Permian components show a $20\text{--}30^\circ$ cumulative counterclockwise offset with respect to the Indo-Pakistan apparent polar wander path. (D) A component of low inclination and predominantly east-west declination, which is observed only in rocks of pre-Panjal Traps age. A secondary origin associated with extrusion of the Panjal Traps flows is surmised. The Triassic and Late Permian primary component directions are predominantly of normal polarity. This suggests a pre-Punjabian (Late Permian) upper age limit for the Permo-Carboniferous (Kiaman) reversed polarity interval. (44 refs.)

78424 Palaeomagnetism of red beds of Early Devonian age from Central Iran. H.Wensink (Dept. of Structural Geology, Utrecht State Univ., Utrecht, Netherlands).

Earth & Planet. Sci. Lett. (Netherlands), vol.63, no.2, p.325-34 (May 1983). Palaeomagnetic results are reported from 13 sites of red beds of Early Devonian age from Central Iran. Detailed palaeomagnetic analyses were carried out. Two types of partial progressive demagnetization were applied, one using alternating magnetic fields, the other heating. These procedures resulted in the detection of the characteristic remanences with a mean direction with $D=24.2^\circ$, $I=1.3^\circ$ ($\alpha_{95}=10.1^\circ$). The palaeomagnetic pole is located at 51.3°N , 163.7°W . If one shifts the Iranian landmass to its most likely position in the Gondwana configuration, then the position of the palaeomagnetic pole coincides with the alternative polar wander path which crossed South America in early Middle Paleozoic times. (23 refs.)

78425 Geomagnetic field analysis. I. Stochastic inversion. D.Gubbins (Bullard Labs., Univ. of Cambridge, Cambridge, England).

Geophys. J. R. Astron. Soc. (GB), vol.73, no.3, p.641-52 (June 1983). Most of the Earth's magnetic field and its secular change originate in the core. Provided the mantle can be treated as an electric insulator, stochastic inversion enables surface observations to be analysed for the core field. A priori information about the variation of the field at the core boundary leads to very stringent conditions at the Earth's surface. The field models are identical with those derived from the method of harmonic splines (Shure, Parker and Backus, 1982) provided the a priori information is specified appropriately. The method is applied to secular variation data from 106 magnetic observatories. The hypothesis that magnetic fields are frozen to the core fluid implies that certain integrals of the secular variation vanish. This idea is tested by computing the integrals and their standard and maximum errors. (18 refs.)

78426 The spatial scale of correlation of the day-to-day variability of S_q . D.M.Schlapp, R.J.Mann (Phys. Dept., Univ. of Exeter, Exeter, England). *Geophys. J. R. Astron. Soc. (GB)*, vol.73, no.3, p.671-3 (June 1983). It is confirmed that even when disturbance variations are taken into account, the spatial scale of day-to-day variability of S_q is local, that is, of the order of one or two thousand kilometres, rather than globally correlated. (5 refs.)

78427 Use of the frozen flux approximation in the interpretation of archaeomagnetic and palaeomagnetic data. D.Gubbins (Bullard Labs., Univ. of Cambridge, Cambridge, England), N.Roberts. *Geophys. J. R. Astron. Soc. (GB)*, vol.73, no.3, p.675-87 (June 1983). The frozen flux approximation of Roberts and Scott (1965) is a constraint on the core field that can be used to aid interpretation of the very sparse datasets that palaeomagnetism and archaeomagnetism provide. It gives bounds on the size of the components of the magnetic field at a point of the Gauss coefficients, and, if valid over such long time periods, limits the shape of the field during transitions between normal and reversed polarities. The maximum intensity at a point consistent with the present flux is 281 μT or 4 times the maximum field observed today. The present dipole is about 50 per cent of its upper bound. Polarity reversal is impossible if the transition field is purely axisymmetric. None of the measurements considered violate the frozen flux approximation. (23 refs.)

78428 Lower Jurassic magnetostratigraphy at the Breggia Gorge (Ticino, Switzerland) and Alpe Turati (Como, Italy). F.Horner, F.Heller (Inst. fur Geophys., ETH-Honggerberg, Zurich, Switzerland). *Geophys. J. R. Astron. Soc. (GB)*, vol.73, no.3, p.705-18 (June 1983). The Breggia gorge (Ticino, Switzerland) provides a continuous outcrop of Mesozoic limestones covering the time between the Lower Jurassic and Upper Cretaceous. The Jurassic section from the Lower Pliensbachian to Aalenian is well dated by ammonites. The limestones of these stages are a good quality recorder of the polarity of the geomagnetic field during this time interval. More than 500 cores have been drilled along a 120 m thick section with a median distance between cores of about 20 cm. Detailed thermal and AF demagnetization and further rock magnetic studies are used to determine the characteristic NRM direction for each sample. Initial NRM intensities and low field susceptibilities reflect variations in oxidation potential and sedimentation rate during carbonate deposition. (36 refs.)

78429 Distorting effects during electromagnetic sounding of horizontally non-uniform media using an artificial field source. A.N.Kuznetsov (All Union Sci. Res. Inst. of Geophys. Methods of Exploration, USSR). *Izv. Acad. Sci. USSR. Phys. Solid Earth (USA)*, vol.18, no.2 (1982). Translation of: *Izv. Akad. Nauk SSSR Fiz. Zemli*, vol.18, no.2, p.130-7 (1982). Specific behavior of different field components of an electrosounding instrument in a horizontally non-uniform medium is studied. Distortions of the electromagnetic field are classified. (5 refs.)

78430 Late Precambrian Keweenaw asymmetric polarities as analyzed by axial offset dipole geomagnetic models. H.Nevanlinna (Dept. of Geophys., Univ. of Helsinki, Helsinki, Finland), L.J.Pesonen. *J. Geophys. Res. (USA)*, vol.88, no.B1, p.645-58 (10 Jan. 1983). [received: May 1983] The Great Logan Paleomagnetic Loop has been interpreted to be a paleomagnetic signature of the North American plate motion during the Keweenaw igneous activity (1200-1000 Ma). However, the presence of three successive asymmetric polarities, along with new geochemical data from the Mamaine Point area, makes this interpretation untenable. A new interpretation is presented according to which the asymmetric polarities represent long-term zonal nondipole geomagnetic field components. Wilson's single-dipole offset model can in general explain the inclination asymmetries, but it yields intensity ratios (reversed/normal) significantly lower than those observed. A coaxial two-dipole model is proposed that better takes into account the observed intensity data. This model consists of a geocentric dipole and an offset dipole located at the core-mantle boundary. A new interpretation for the evolution of the Logan Loop is described according to which at least 50% of the hairpin-shaped loop is produced by oscillation of the dipole strength ratio. Apparent polar wander (APW) is still evident, but the shape of the loop and the APW speed along the loop is reduced. (44 refs.)

78431 Geomagnetic spherical harmonic analyses. I. Techniques. D.R.Schmitz (Colorado School of Mines, Golden, CO, USA), J.C.Cain. *J. Geophys. Res. (USA)*, vol.88, no.B2, p.1222-8 (10 Feb. 1983). Improved techniques for direct least squares analysis of the main geomagnetic field are introduced and tested with simulated data. One improvement involves adding secular change data to the least squares analysis (as well as the usual spatial data). As a result, the secular variation (SV), as observed at fixed magnetic observatories and repeat stations, directly adjusts the SV terms of the spherical harmonic coefficients, while spatial data adjust both the spatial and SV terms. Simulations show that SV errors can be reduced by factors of 2 or 3 by introducing SV as data. The second refinement involved obtaining uncorrelated spherical harmonic coefficient sets through employment of a uniform distribution of data by area or by a compromise of an area-weighting scheme. The latter was shown to reduce high cross correlations between spherical harmonic coefficients by up to a factor of 3 in simulated tests. (14 refs.)

78432 Core and crustal geomagnetic fields. L.R.Aldredge (US Geological Survey, Denver, CO, USA). *J. Geophys. Res. (USA)*, vol.88, no.B2, p.1229-34 (10 Feb. 1983). The spherical harmonic content of fields from core sources and that from extended crustal sources overlap so much that very long wavelength anomalies obtained by subtracting a core field model up to only degree 10 from the observations will be distorted so badly that interpretation in terms of geological sources will be difficult. (10 refs.)

78433 Statistical averaging of marine magnetic anomalies and the aging of oceanic crust. R.J.Blakely (US Geological Survey, Menlo Park, CA, USA). *J. Geophys. Res. (USA)*, vol.88, no.B3, p.2289-96 (10 March 1983). Visual comparison of Mesozoic and Cenozoic magnetic anomalies in the North Pacific suggests that older anomalies contain less short-wavelength information than younger anomalies in this area. To test this observation, magnetic profiles from the North Pacific are examined from crust of three ages: 0-2.1, 29.3-33.1, and 64.9-70.3 my BP. The results are interpreted using a multilayer model for marine magnetic anomalies in which the upper layer, corresponding to pillow basalt of seismic layer 2A, acts as a source of noise to the magnetic anomalies. As the ocean crust ages, this noisy contribution by the pillow basalts becomes less significant to the anomalies. Consequently, magnetic sources below layer 2A must be faithful recorders of geomagnetic reversals. (36 refs.)

78434 High paleointensities of the geomagnetic field from thermomagnetic studies on rift valley pillow basalts from the Mid-Atlantic Ridge. M.Prevot, E.A.Mankinen, S.Gromme (US Geological Survey, Menlo Park, CA, USA), A.Lecailla. *J. Geophys. Res. (USA)*, vol.88, no.B3, p.2316-26 (10 March 1983). Nineteen pillow basalts dredged within the rift valley of the Mid-Atlantic Ridge at 36.8°N were studied by the Thellier stepwise heating method in order to determine the paleointensity of the geomagnetic field when they erupted on to the sea floor. Previously reported fission track ages are 2000 to 6000 years for the youngest rocks (mainly olivine basalts) and 10000 to 100000 years for the others (mainly plagioclase basalts and pyroxene basalts). The accuracy and validity of this method of paleointensity determination is discussed. The palaeo intensity results suggest that the latest eruptions on the inner floor of the Rift Valley at 36.8°N occurred 1500 \pm 1000 years ago. (55 refs.)

78435 Paleomagnetism of Carboniferous intrusions in North Carolina. C.Barton, L.Brown (Dept. of Geology & Geography, Univ. of Massachusetts, Amherst, MA, USA). *J. Geophys. Res. (USA)*, vol.88, no.B3, p.2327-35 (10 March 1983). Paleomagnetic samples of two late Paleozoic plutons were collected from the eastern Piedmont Province in North Carolina. Results from the early Carboniferous (326 \pm 27 m.y.) Lilesville pluton, located in the Carolina Slate Belt, indicate a pole position similar to that of the stable North American craton for the lower Carboniferous. The late Carboniferous Churchland pluton, located in the Charlotte Belt, gives a pole of 34°N, 126°E which correlates well with other North American poles for the late Carboniferous. Observations made by Kent and Opdyke (1978) on rocks from the eastern edge of the northern Appalachians suggest gross lateral displacement between the mid-Devonian and late Carboniferous in the late Paleozoic. This paleomagnetic information from the eastern Piedmont regions implies that the area of the Carolina Slate Belt and Charlotte Belt was associated with the North American platform for the entire Carboniferous period. (42 refs.)

78436 Hotspot-spin axis motion or magnetic far-sided effect? D.Epp, W.W.Sager, F.Theyer (Hawaii Inst. of Geophys., Univ. of Hawaii, Honolulu, HI, USA), S.R.Hammond. *Nature (GB)*, vol.303, no.5915, p.318-20 (26 May 1983). Paleomagnetic data from central Pacific sediments and from the Hawaiian-Emperor volcanic chain indicate that, during the Tertiary, either the derived magnetic pole was located alternately on the far and near side of the geographical pole, or that the hotspot coordinate systems (thought to be fixed relative to the Earth's mantle) oscillated relative to the Earth's spin axis. (23 refs.)

78437 Local contributions to the M_2 lunar geomagnetic variations in the south-west of England. A.M.Hart, C.D.Honebon, W.G.V.Rosser (Phys. Dept., Exeter Univ., Exeter, England). *Phys. Earth & Planet. Inter. (Netherlands)*, vol.32, no.1, p.60-4 (April 1983). By comparing the M_2 lunar geomagnetic variations of 12.42 h period at Sidmouth and Exeter, it is shown that local concentrations of the electric currents, induced by sea tides in the seas and oceans around the UK, can give a significant contribution to the M_2 variations at the two observatories. (4 refs.)

78438 Analogue model study of electromagnetic induction in the Newfoundland region. D.Hebert, H.W.Dosso, W.Nienaber (Dept. of Phys., Univ. of Victoria, Victoria, Canada), J.A.Wright. *Phys. Earth & Planet. Inter. (Netherlands)*, vol.32, no.1, p.65-84 (April 1983). The behaviour of magnetic field variations over the Newfoundland, Canada region is studied using a scaled laboratory analogue model. The model source frequencies used simulate periods of 100 s, 300 s, 900 s, and 1800 s. Large anomalous in-phase and quadrature model magnetic fields are observed over the Strait of Belle Isle and Cabot Strait. The 'cape effect', that is, the large field enhancements due to deflection of induced current at capes, is observed for all four periods. The magnitudes and directions of inter-station induction arrows and single station induction arrows are studied. The coastal effects would not produce serious perturbations to the field measured over crustal anomalies within the central regions of Newfoundland. (23 refs.)

78439 Paleomagnetism of some Precambrian rocks in south-east Greenland. G.E.J.Beckmann (School of Phys., Newcastle upon Tyne Univ., Newcastle upon Tyne, England). *Phys. Earth & Planet. Inter. (Netherlands)*, vol.32, no.1, p.85-99 (April 1983). A palaeomagnetic pole is established at 25.1°N 273.9°E ($dp=10.6^\circ$, $dm=14.3^\circ$) from the norite-charnockite complex at Angmagssalik, emplaced at 1800 Ma. A somewhat older palaeomagnetic pole at 4.2°S 246.7°E ($dp=4.2^\circ$, $dm=8.3^\circ$) is obtained from Archaean gneisses close to the northern boundary of the Nagssugtoqidian mobile belt where reversals of magnetization are present. Both magnetizations were imposed during slow cooling following the Nagssugtoqidian metamorphism. (28 refs.)

78440 The electromagnetic field of S_q variations. V.V.Aksenov (Sci. Res. Inst. of Systems, Novosibirsk, USSR). *Sov. Geol. & Geophys. (USA)*, vol.23, no.3, p.80-4 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.3, p.90-6 (1982). Discusses the problem of the structure and composition of the electromagnetic field of S_q variations. It is shown that it consists of two types of fields: magnetic and electrical. Their tensions in magnetic components are comparable, but in the electrical components the electrical field is significantly greater. (9 refs.)

91.30 SEISMOLOGY

- 78441 High frequency radiation from dynamic earthquake fault models.** R. Madariaga (Dept. de Sci. de la Terre, Univ. Paris VII, Paris, France). *Ann. Geophys. (France)*, vol.1, no.1, p.17-23 (Jan.-Feb. 1983).
 Studies the radiation of high frequency waves from a simple antiplane model of an earthquake source. In this model only antiplane waves are generated so that the mathematics is relatively simple, but the physics is the same as in the more complex plane of three dimensional models where P and S waves are radiated. An exact solution is found for the problem of an arbitrarily moving semi-infinite crack in the presence of a general dynamic stress drop. In the case when friction is independent of time, an algebraic expression is obtained for particle velocity. This result is exploited to understand the origin of high frequency waves, and the role of rupture velocity and stress intensity on the radiation. The author shows that barriers and asperities dominate the radiation, but that they are indistinguishable from a high frequency point of view. (16 refs.)
- 78442 An aftershock study of the El Asnam (Algeria) earthquake of 1980 October 10.** M. Oued (Lab. de Geophys. Interne, Univ. Sci. et Médicale de Grenoble, Grenoble, France), G. Yielding, D. Hatzfeld, G. C. P. King. *Geophys. J. R. Astron. Soc. (GB)*, vol.73, no.3, p.605-39 (June 1983).
 An array of 28 portable seismic stations was operated in the region of El Asnam following the magnitude 7.3 (M_s) thrust earthquake of 1980 October 10. Locations of 494 events are presented and provide an indication of the overall form of the aftershock distribution. Tests to establish location accuracy (particularly depth) reduce this set to 277 events which, it is argued, are well constrained. P-waves alone are used in this study as a consequence of a debate about the reliability of reading S-phases. From the reduced set of 277 events, 81 events provide well-constrained focal mechanisms. The locations are presented in the form of maps and cross-sections, and discussed in relation to information already derived from field mapping of surface breaks and teleseismic studies of the waveforms of the main event. (32 refs.)
- 78443 Spatial distribution of microearthquakes beneath the Japan Trench from ocean bottom seismographic observations.** N. Hirata, T. Yamada (Geophys. Inst., Univ. of Tokyo, Tokyo, Japan), H. Shimamura, H. Inatani, K. Suyehiro. *Geophys. J. R. Astron. Soc. (GB)*, vol.73, no.3, p.653-69 (June 1983).
 The area of the Japan Trench, about 40°N off the Tohoku District of north-eastern Honshu, Japan, was for the first time extensively covered by an ocean bottom seismograph (OBS) array. Hypocentres are calculated by using a generalized inversion technique. Sixty-five events, mostly with magnitudes from 1.5 to 3.0, which were not located by a land network, were determined to be within or near the area covered by the OBS array. The OBS array enabled the authors to determine the focal depth of microearthquake activity with better resolution than was previously possible. The authors report the first direct observations to clarify the spatial distribution of microearthquakes associated with the bending and/or subducting of the oceanic plate just beneath the Japan Trench axis. (46 refs.)
- 78444 Source mechanism and surface wave excitation for two earthquakes in northern Baja California, Mexico.** F. A. Nava (Univ. Nacional Autónoma de México, México City, México), J. N. Brune. *Geophys. J. R. Astron. Soc. (GB)*, vol.73, no.3, p.739-63 (June 1983).
 Two earthquakes of comparable local magnitude from different regions of northern Baja California (the 1975 July 17 Pino Solo earthquake, $M_L=5.1$, from the Peninsular Ranges region, and the 1976 December 7 Mesa de Andrade earthquake, $M_L=5.3$, from the Colorado River Delta region) are studied in detail to determine possible causes for the observed stronger excitation of surface waves by earthquakes from the Delta region relative to earthquakes of comparable local magnitude in the Peninsular Ranges region. Data from distant stations are complemented with data from aftershock studies using local arrays and, for the Mesa de Andrade earthquake, with data from two strong motion stations. (36 refs.)
- 78445 Group velocity distribution of surface waves in the North Atlantic.** T. B. Yanovskaya (Faculty of Phys., Leningrad State Univ., Leningrad, USSR). *Izv. Acad. Sci. USSR, Phys. Solid Earth (USA)*, vol.18, no.2 (1982). Translation of: *Izv. Akad. Nauk SSSR Fiz. Zemli*, vol.18, no.2, p.83-9 (1982).
 A smoothed velocity distribution of Rayleigh waves with periods of 20, 30, 40, 50 and 60 sec in the North Atlantic is obtained by the Backus-Gilbert (1968) method. At depths corresponding to the penetration of waves with periods of 20 to 30 sec a sharp asymmetry of the lithosphere structure manifests itself to the west and to the east of the mid-oceanic ridge. At greater periods a rift zone is revealed as a region of low surface wave velocities. (8 refs.)
- 78446 Elastic-wave radiation during a camouflaged explosion.** S. Z. Dunin, O. V. Nagornov, Ye. A. Popov (Moscow Engng. & Phys. Inst., Moscow, USSR). *Izv. Acad. Sci. USSR, Phys. Solid Earth (USA)*, vol.18, no.2 (1982). Translation of: *Izv. Akad. Nauk SSSR Fiz. Zemli*, vol.18, no.2, p.98-103 (1982).
 The problem of elastic-wave radiation during an explosion in a porous medium is considered with allowance for the dilatancy effect. The character of the elastic-energy radiation at various moments of time is investigated. An analysis is made of the spectral composition of the radiated seismic signal, and of the effect of the strength parameters of this medium, the porosity and the dilatancy coefficient on the magnitude of the elastic energy radiated during an explosion. (14 refs.)
- 78447 New characteristics of the focal extent of near earthquakes.** I. V. Gorbunova, Z. A. Kal'met'eva (O.Yu. Schmidt Inst. of Earth Phys., Acad. of Sci., USSR). *Izv. Acad. Sci. USSR, Phys. Solid Earth (USA)*, vol.18, no.3, p.188-95 (1982). Translation of: *Izv. Akad. Nauk SSSR Fiz. Zemli*, vol.18, no.3 (1982).
 A new approach to interpretation of P and S waves from near earthquakes, based on a theoretical concept and models of the development of the failure process in the focus, and data on studies of faults during earthquakes, are discussed. Only direct waves at distances of up to 180 km are investigated, since secondary (exchange or reflected) waves do not yet appear on this segment of the path. Short-period equipment with table-type amplitude-frequency response for periods from 0.3 to 1 sec is used. Besides interpretation of the first arrivals of P-waves, which correspond to the incipient rupture

at the earthquake focus, the P_{\max} wave, which is emitted by the focus at the maximum destruction time, is interpreted. (18 refs.)

- 78448 Anelastic response of the Earth to a dip slip earthquake.** H. J. Melosh, A. Raefsky (Earth & Space Sci. Dept., State Univ. of New York, Stony Brook, NY, USA). *J. Geophys. Res. (USA)*, vol.88, no.B1, p.515-26 (10 Jan. 1983). [received: May 1983]
 The deformation of the Earth's surface immediately following an earthquake is well modeled by a dislocation in an elastic half space. Some time after the event, however, the elastic stresses begin to relax due to flow in the more fluid regions of the upper mantle (the asthenosphere). This relaxation causes further slow displacements observable at the Earth's surface. This paper examines the pattern and timing of these postseismic motions for a vertical dip slip fault and a 30° dip thrust fault. A variety of rheological models are studied. These models encompass variations in asthenosphere thickness, mesosphere viscosity, fault depth, and, most important, power law flow. (43 refs.)
- 78449 Regionalization of crustal coda Q in the continental United States.** S. Singh, R. B. Herrmann (Dept. of Earth & Atmospheric Sci., Saint Louis Univ., Saint Louis, MO, USA). *J. Geophys. Res. (USA)*, vol.88, no.B1, p.527-38 (10 Jan. 1983). [received: May 1983]
 A contour map of crustal Q_0 values for the entire United States is presented based on a scattering model to explain the coda waves of local and near regional earthquakes. These coda Q_0 values are in good agreement with Q of Lg waves. Data are obtained from over 250 local earthquakes, with most magnitudes between 3.0 and 5.0, recorded by 25 WWSSN and 27 LRSM stations throughout the continental United States. These two sets of data provide a range of frequencies from 0.5 to 3.5 Hz. A frequency dependence of Q is observed in the range of frequencies considered. A power law dependence of the form $Q = Q_0(f/f_0)^n$ is assumed. The value of frequency dependence is found to be maximum in the tectonically active western United States and least in the stable regions of the central and south central United States. The lowest Q_0 values are obtained in the western United States. (46 refs.)
- 78450 Strain dependent attenuation: observations and a proposed mechanism.** R. R. Stewart, M. N. Toksoz (Dept. of Earth & Planetary Sci., MIT, Cambridge, MA, USA), A. Timur. *J. Geophys. Res. (USA)*, vol.88, no.B1, p.546-54 (10 Jan. 1983). [received: May 1983]
 The measured attenuation (Q^{-1}) of a rock is a function of a number of parameters, one of those being the applied strain amplitude. Near source (large strain) wave propagation may behave highly non-linearly, and the strain amplitude dependence can provide insight into the attenuation mechanism. A physical model based on the contact friction between crack surfaces in the rock has been developed to describe rock deformation and dissipation under large applied strain. The three-dimensional crack surfaces are characterized by a statistical distribution of asperity heights. The sliding contact of these spherically-tipped asperities dissipates frictional energy. The results of ultrasonic pulse transmission experiments on sandstone and lucite are compared with the model's prediction. (33 refs.)
- 78451 Focal depths and fault plane solutions of earthquakes under the Tibetan Plateau.** P. Molnar (Dept. of Earth & Planetary Sci., MIT, Cambridge, MA, USA), Wang-Ping Chen. *J. Geophys. Res. (USA)*, vol.88, no.B2, p.1180-96 (10 Feb. 1983).
 Compares synthetic and recorded P waveforms to place constraints on the focal depths and fault plane solutions of 16 crustal earthquakes beneath the highest parts (>4000 m) of the Tibetan Plateau. Fault plane solutions for all 16 events show combinations of normal and strike slip faulting with T axes oriented approximately east-west. None of these solutions show thrust faulting. Thus the data corroborate previous inferences that the active tectonics are dominated by east-west extension. Focal depths for all 16 events are less than 15 km and appear to be between 5 and 10 km. This style of deformation and these depths of faulting are similar to those in the Basin and Range province of the western United States. Two intermediate depth events below the crust of southern Tibet occurred in the mantle beneath a thick, aseismic lower crust. Their occurrence suggests that brittle deformation occurs there in response to a stress field similar to that operating at shallow depths beneath Tibet. (29 refs.)
- 78452 Some statistical properties of a sequence of historical Calabro-Peloritan earthquakes.** A. Bottari, G. Neri (Istituto Geofisico e Geodetico, Univ. di Messina, Messina, Italy). *J. Geophys. Res. (USA)*, vol.88, no.B2, p.1209-12 (10 Feb. 1983).
 A statistical analysis is applied to the sequence of earthquakes, with epicentral intensity $I_0 \geq VIII$ MSK, which occurred in the Calabro-Peloritan Arc region (southern Italy) during the period 1600-1974. The study reveals, by the application of the Poisson test, an evident level of interdependence of the shocks which appear grouped in temporal clusters satisfying the simple Poisson process. In fact, the equations which characterize the generalized Poisson process give a good fit of the observed data, the distribution of the events in the clusters being of the Pareto type (discrete). The values 0.90 and 2.8 have been found for k' and E parameters, which are the average number of clusters occurring in unit time and the parameter of the Pareto distribution, respectively. A subsequent elaboration of these results makes the calculation of some quantities, like the clustering length, possible. (17 refs.)
- 78453 Assigning probability gain for precursors of four large Chinese earthquakes.** T. Cao, K. Aki (Dept. of Earth & Planetary Sci., MIT, Cambridge, MA, USA). *J. Geophys. Res. (USA)*, vol.88, no.B3, p.2185-90 (10 March 1983).
 The concept of probability gain associated with a precursor (Aki, 1981) is extended to a set of precursors which may be mutually dependent. Making use of a new formula, the authors derive a criterion for selecting precursors from a given data set in order to calculate the probability gain. The probabilities per unit time immediately before four large Chinese earthquakes are calculated. They are approximately 0.09, 0.09, 0.07 and 0.08 per day for 1975 Haicheng ($M=7.3$), 1976 Tangshan ($M=7.8$), 1976 Longling ($M=7.6$), and Songpan ($M=7.2$) earthquakes, respectively. These results are encouraging because they suggest that the investigated precursory phenomena may have included the complete information for earthquake prediction, at least for the above earthquakes. With this method, the step-by-step approach to prediction used in China may be quantified in terms of the possibility of earthquake occurrence. (31 refs.)
- 78454 Source times and scaling relations of large earthquakes.** M. Furumoto (Dept. of Earth Sci., Nagoya Univ., Nagoya, Japan). *J. Geophys. Res. (USA)*, vol.88, no.B3, p.2191-8 (10 March 1983).
 Source time is a kinetic fault parameter corresponding to the duration of seismic source time functions and is accurately determined from phase spectra of long-period surface waves. Source times are determined for 36 large earthquakes during the last three decades. Scaling relations among source times, seismic moments, and fault dimensions are derived. Seismic moment is pro-

portional to the cube of source time, and fault dimension is proportional to source time. Source times for low-angle thrust earthquakes along deep-sea trenches are found to be longer than those of other types, such as intraplate shocks and deep shocks. They are also significantly longer than the rupture times expected from a Haskell model, suggesting that, generally, there exists an introductory stage of faulting that precedes the main stage of the rupture propagation. (35 refs.)

78455 A teleseismic analysis of the New Brunswick earthquake of January 9, 1982. G.L.Choy (US Geological Survey, Denver, CO, USA), J.Boatwright, J.W.Dewey, S.A.Sipkin. *J. Geophys. Res. (USA)*, vol.88, no.B3, p.2199-212 (10 March 1983).

The analysis of the $m_{5.7}$ New Brunswick earthquake of January 9, 1982, has important implications for the evaluation of seismic hazards in eastern North America. Source characteristics of this earthquake have been determined from analysis of data that were digitally recorded by the Global Digital Seismograph Network. From broadband displacement and velocity records of P waves, a dynamic description of the rupture process as well as conventional static properties of the source have been determined. The depth of the hypocenter is estimated to be 9 km from depth phases. The focal mechanism determined from the broadband data corresponds to predominantly thrust faulting. From the variation in the waveforms the direction of slip is inferred to be up-dip on a west dipping NNE striking fault plane. The steep dip of the inferred fault plane suggests that the earthquake occurred on a preexisting fault that was at one time a normal fault. The estimated rupture length is 5.5 km. (40 refs.)

78456 Seismicity near Palmdale, California, and its relation to strain changes. J.Sauber, K.M.Nally, J.C.Pechmann, H.Kanamori (Seismological Lab., California Inst. of Technol., Pasadena, CA, USA).

J. Geophys. Res. (USA), vol.88, no.B3, p.2213-19 (10 March 1983). Evaluates the relationships between the spatio-temporal patterns and faulting mechanisms of small earthquakes and the recent temporal changes in horizontal strain observed along the 'big bend' portion of the San Andreas fault near Palmdale, California. Microearthquake activity along the entire big bend of the San Andreas fault increased in November 1976 concurrent with the initiation of an earthquake swarm at Juniper Hills. This activity then decreased abruptly to the northwest and southeast of Juniper Hills during the beginning of 1979. This drop in seismic activity occurred around the time that crustal dilatation was observed on the US Geological Survey Palmdale trilateration network. Focal mechanisms from the study region are predominantly thrust. There are two time periods when the mechanisms are closer to strike slip than to thrust. The first period corresponds to the beginning of the Juniper Hills swarm. The second period approximately coincides with a change in trend of the strain data from uniaxial N-S compression to dilatation. (14 refs.)

78457 Three-dimensional crust and upper mantle structure at the Nevada Test Site. S.R.Taylor (Lawrence Livermore Nat. Lab., Livermore, CA, USA).

J. Geophys. Res. (USA), vol.88, no.B3, p.2220-32 (10 March 1983). The three-dimensional crust and upper mantle structure at the Nevada Test Site (NTS) is derived by combining teleseismic P wave travel time residuals with P_n source time terms. The NTS time terms and relative teleseismic residuals are calculated by treating the explosions at a network of 'receivers' which record 'shots' located at the surrounding stations. Average relative teleseismic P wave residuals show a consistent progression of positive (late arrivals) to negative residuals from east to west across the NTS. However, P_n time terms beneath Rainier Mesa are at least 0.3 and 0.5 s less than those beneath Pahute Mesa and Yucca flat, respectively, indicating the Pahute Mesa are surprisingly uniform, and the largest time terms and residuals are observed in the northwest and southern parts of Yucca Flat. (52 refs.)

78458 Rayleigh waves excited by the discontinuous advance of a rupture front. J.G.Harris (Theoretical & Appl. Mech., Univ. of Illinois, Urbana, IL, USA), J.D.Achenbach, A.N.Norris.

J. Geophys. Res. (USA), vol.88, no.B3, p.2233-9 (10 March 1983). Analytical results are presented for Rayleigh waves excited by a sudden change in the rate of growth of a subsurface zone of rupture. The curved rupture front advances across an inclined plane. The rupture can be brittle or cohesive tractions can act at its front. The analysis consists of two parts: First, ray theory is used to calculate wavefront approximations to the waves emitted when the rupture front speed suddenly changes. Secondly, a representation integral for the Rayleigh wave, where the integration is performed over a surface enclosing the rupture front, is constructed by using the emitted waves in combination with an appropriate Green's tensor. This integral is evaluated asymptotically. Synthetic accelerographs are constructed which illustrate how the rupture process, and the geometry of the rupture front and the fault plane affect the excitation of Rayleigh waves. (9 refs.)

78459 Viscoelastic stress relaxation on deep fault sections as a possible source of very long period elastic waves. M.Bonafede, E.Boschi (Istituto di Geofisica, Univ. di Bologna, Bologna, Italy), M.Dragoni.

J. Geophys. Res. (USA), vol.88, no.B3, p.2251-60 (10 March 1983). Observations of very long elastic waves are attributed to 'silent' earthquakes, events which are presumed to occur at depth in a nonbrittle regime. The fault at depth is modeled as a thin viscoelastic gouge layer embedded in an elastic medium. The source of silent earthquakes is envisaged as a prolonged, slow slippage of the fault faces, which yields a radiation spectrum strongly depleted in the high-frequency components and dominated by the near-field term. The results of the model are compared with the dominant frequencies, mean duration, and amplitude of a long-period perturbation recorded at Trieste in the years preceding the 1976 Friuli (Italy) earthquake. The role that silent earthquakes may play in the overall earthquake mechanism (in particular, as precursory phenomena) is discussed. (73 refs.)

78460 Three-dimensional crust and upper mantle structure of the Eurasian continent. C.-C.Feng, T.-L.Teng (Dept. of Geological Sci., Univ. of Southern California, Los Angeles, CA, USA).

J. Geophys. Res. (USA), vol.88, no.B3, p.2261-72 (10 March 1983). Group velocities of fundamental mode Rayleigh waves of 109 wave paths within Eurasia have been measured by an improved frequency-time analysis technique. Stochastic inversion theory is applied to the mixed-path measurements to extract pure path group velocities of $10^\circ \times 10^\circ$ grid elements that form the subdivisions of Eurasia. Then a three-dimensional crust and upper mantle structure of the Eurasian continent to a depth of 300 km is constructed. The average crustal thickness of Eurasia is found to be about 40 km. Abnormally thick crust from 50 to 65 km is obtained in areas of Tien Shan, the Altai mountains, Afghanistan, Pamir, Tibet, and Burma. (25 refs.)

78461 The geoid, small-scale convection, and differential travel time anomalies of shear waves in the central Indian Ocean. M.Stark, D.W.Forsyth (Dept. of Geological Sci., Brown Univ., Providence, RI, USA).

J. Geophys. Res. (USA), vol.88, no.B3, p.2273-88 (10 March 1983). 37 differential travel times have been measured for the phase pairs SS-S, sSS-sS, ScS2-ScS, ScS2-S, sScS2-sScS, and sScS2-sS. Each pair included a surface bounce point in the central Indian Ocean between 4°N and 21°S and

69° and 85°E . Residuals were calculated relative to both the J-B travel time tables and the PEM-C Earth model and were corrected for the elevation of the bounce points. The mean J-B residual associated with bounce points in the Central Indian Basin is -2.8 ± 0.7 s (fast). This is similar to the -4.0 s found for old continental nuclei. After correcting for known differences between continental and oceanic crustal structure and for differences in measurement technique, it was found that travel times in the mantle beneath the Central Indian Basin are midway in character between those beneath pre-Cambrian shields and those beneath the western Pacific ocean basin. The fastest differential travel times occur along a line passing close to the center of the large Indian Ocean geoidal low. There is a clear increase in travel time with distance from the center of the geoid low. The Chagos-Laccadive Ridge seems to coincide with a transition from the fast differential travel times of the Central Indian Basin to slower differential travel times associated with bounce points beneath young seafloor near active spreading centers. (45 refs.)

78462 Velocity and attenuation anisotropy in deep-sea carbonate sediments. D.-C.Kim, K.W.Katahara, M.H.Manghani, S.O.Schlanger (Hawaii Inst. of Geophys., Univ. of Hawaii, Honolulu, HI, USA).

J. Geophys. Res. (USA), vol.88, no.B3, p.237-43 (10 March 1983). Laboratory studies have been carried out to determine the causes of velocity and attenuation anisotropy in pelagic carbonate sediments from Deep Sea Drilling Project site 288 on the Ontong-Java Plateau. Compressional velocity V_p was measured under independently controlled pore pressure and confining pressure. Velocity anisotropy for compressional waves (horizontal velocity $>$ vertical velocity) is found to decrease with increasing effective pressure, i.e. with closure of pores. The present results indicate that preferred horizontal orientation of grain contacts and flat pores is also a significant cause of the observed anisotropy for many samples. Significant anisotropy in ultrasonic attenuation for compressional (Q_p^{-1}) and shear (Q_s^{-1}) waves is observed such that the losses are greatest for propagation modes that can generate relative motion across horizontal grain contacts or flat horizontal pores. The results are discussed in terms of the possible mechanisms of dissipation. (26 refs.)

78463 In situ studies of velocity in fractured crystalline rocks. D.Moos (Dept. of Geophys., Stanford Univ., Stanford, CA, USA), M.D.Zoback.

J. Geophys. Res. (USA), vol.88, no.B3, p.2345-58 (10 March 1983). A study of the effects of macroscopic fractures on P and S wave velocities has been conducted in four wells drilled in granitic rock to depths between 0.6 and 1.2 km. The effect of macroscopic fractures is to decrease both V_p and V_s and increase V_p/V_s . In wells with a relatively low density of macroscopic fractures, the in situ velocity is similar to that of saturated core samples under confining pressure in the laboratory, and there is a clear correlation between zones with macroscopic fractures and anomalously low velocities. In wells with numerous macroscopic fractures, the in situ velocity is lower than that of intact samples under pressure, and there is a correlation between the rate at which in situ velocity increases with depth and the rate at which the velocity of laboratory samples increase with pressure. Differences in in situ P wave velocity between wells cannot be explained solely by differences in the degree of macroscopic fracturing, thus emphasizing the importance of composition and microcracks on velocity. Chemical alteration of rock adjacent to macroscopic fractures appears to play an important role in reducing in situ velocities. (33 refs.)

78464 Scattering of Rayleigh waves by a rectangular rough surface.

T.Momoi (Earthquake Res. Inst., Univ. of Tokyo, Tokyo, Japan). *J. Phys. Earth (Japan)*, vol.30, no.4, p.295-319 (1982).

A theoretical study is made on the scattering of Rayleigh waves which are incident to a rectangular rough surface. The partition of the energy flux of the waves scattered by a mountain is obtained. It is then revealed that resonant standing Rayleigh waves occurring along the top surface of the rectangular mountain enhance the transmissivity of incident Rayleigh waves when the mountain is low ($L/B \leq 0.7$) while suppressing the transmissivity when the mountain is high ($L/B \geq 0.8$), where L and B are the height and half-width of the mountain. When the mountain is high, resonant standing Rayleigh waves occur along the vertical cliff in the case of $kB < 1$ (k : wave number of S waves). The generation of these standing waves remarkably suppresses the transmissivity of incident Rayleigh waves through the mountain. As for the directivity of the scattered body waves (case of $L/B = 0.5$), they are transmitted away, mainly by S waves, vertically downwards when $kB \leq 1$ and toward the leeward quarter space when $kB > 1$. (18 refs.)

78465 Magnitude, seismic moment and apparent stress for major deep earthquakes. K.Abe (Dept. of Geophys., Hokkaido Univ., Sapporo, Japan).

J. Phys. Earth (Japan), vol.30, no.4, p.321-30 (1982). On the basis of an extensive data-set of major deep and intermediate-depth earthquakes, the relation between body-wave magnitude m_B and seismic moment M_0 is discussed in terms of apparent stress. m_B is determined from amplitudes and periods of P , PP and S waves recorded by broad-band instruments, and is therefore suitable for measuring the overall size of major earthquakes. The relation between m_B and $\log M_0$ is approximately linear for the data set of m_B greater than 6. This indicates that the apparent stress is, on the average, nearly constant. A gross average of 60 bar is obtained for the earthquakes over a large depth range. For a simple fault model, one has $E_s = (7.10^{-3}) M_0$, where E_s is the radiated seismic energy. The constant apparent stress implies a decrease of seismic efficiency with an increase of depth. A very similar relation between m_B and $\log M_0$ is applicable to large shallow earthquakes. (31 refs.)

78466 Effect of Poisson's ratio on elastic wave radiation in a semi-infinite medium. I.Onda (Faculty of Engng., Gunma Univ., Gunma, Japan).

J. Phys. Earth (Japan), vol.30, no.4, p.349-66 (1982). Radiation patterns of elastic waves due to a normal and a horizontal traction applied on a free surface of a semi-infinite medium are discussed in relation to the Poisson's ratio ν . The field is derived by means of the method of steepest descent. The P radiation is much less than the S radiation, and is reduced as ν becomes large. The Rayleigh wave generation diminishes with increasing of ν . The S -radiation factor is complex at the colatitudinal angle θ larger than θ_c , where $\theta_c = \sin^{-1}(S \text{ velocity}/P \text{ velocity})$. The S energy due to a normal traction is mostly radiated at angles larger than θ_c , particularly, if ν is close to 0.5. The S radiation due to a horizontal one has a maximum at an angle θ_1 larger than 45° and vanishes at 45° . (8 refs.)

78467 On the correlation between the syzygies and great earthquakes in Hebei of China. Ren Zhenqiu (Acad. of Meteorological Sci., Central Meteorological Bur. of China, Beijing, China).

Kexue Tongbao (Foreign Lang. Ed.) (China), vol.28, no.1, p.74-9 (Jan. 1983). [received: June 1983]

The author examines the great earthquake ($M_s \geq 6$) record of Hebei Province in China, in conjunction with the lunar phases. Hence the correlation between earthquakes and syzygies in this area is determined. (4 refs.)

78468 Seismicity of Yemen. N.N.Ambraseys, C.P.Melville (Dept. of Civil Engng., Imperial Coll., London, England). *Nature (GB)*, vol.303, no.5915, p.321-3 (26 May 1983). Shows that historical sources of local information describe a fairly continuous occurrence of medium magnitude, damaging shocks over the past 12 centuries, including a destructive event in 1941 that in many respects resembles the earthquake of December 1982. The common presumption that the Arabian Peninsula has a very low seismicity is incorrect. (19 refs.)

78469 Evidence for dyke intrusion earthquake mechanisms near Long Valley caldera, California. B.R.Julian (US Geological Survey, Menlo Park, CA, USA). *Nature (GB)*, vol.303, no.5915, p.323-5 (26 May 1983). A re-analysis of the magnitude 6 earthquakes that occurred near Long Valley caldera in eastern California on 25 and 27 May 1980, suggests that at least two of them, including the largest, were probably caused by fluid injection along nearly vertical surfaces and not by slip on faults. Several investigators have reported difficulty in explaining both the long-period surface-wave amplitudes and phases and the locally recorded shorter-period body-wave first motions from these events, using conventional double-couple (shear fault) source models. It is shown that the data agree well with the predictions for a compensated linear-vector dipole equivalent-force system, with its principal extensional axis, horizontal and trending N 55-65° E. Such a mechanism is what would be expected for fluid injection into dykes striking N 25-35° W, which is the approximate strike of numerous normal faults in the area. (10 refs.)

78470 Phase and group velocities and Q of mantle Love and Rayleigh waves of the first two modes and their azimuthal dependences for the 1963 Kurile Islands earthquake. Y.Fukao, M.Kobayashi (Dept. of Earth Sci., Nagoya Univ., Nagoya, Japan). *Phys. Earth & Planet. Inter. (Netherlands)*, vol.32, no.1, p.4-35 (April 1983). Analyzes phase and group velocities and Q of mantle Love and Rayleigh waves from the 1963 Kurile Islands earthquake ($M_w=8.5$), for both the fundamental and the first higher modes. The period ranges are from 100-500 s for the fundamental modes and from 100-275 s for the first higher modes. Love and Rayleigh waves were extracted from 24 stations. (64 refs.)

78471 Determination of magnitude for large shallow earthquakes 1898-1917. K.Abe (Dept. of Geophys., Faculty of Sci., Hokkaido Univ., Sapporo, Japan). *Phys. Earth & Planet. Inter. (Netherlands)*, vol.32, no.1, p.45-59 (April 1983). In order to arrive at a uniform basis for a study of the global seismicity, the surface-wave magnitude M_s of shallow earthquakes for 1898-1917 is determined by using maximum amplitudes of surface waves recorded by undamped Milne and Omori seismographs. The effective gain of these instruments needs to be calibrated with great care, because of the lack of a damping device. The calibration of Milne instruments is based on a comparison of amplitudes measured by Milne instruments with those by more modern, damped instruments. M_s is determined for a large number of earthquakes between 1898 and 1917. To supplement the data for 1913-1917, records of undamped Omori seismographs are used. For the entire period from 1898 to 1917, 308 shallow earthquakes with $M \geq 7.0$ are listed. Both this list and the previous catalogue of Abe (1981) for 1918-1960 provide a catalogue of large shallow earthquakes much more uniform than any previously established. (23 refs.)

78472 On the localization of seismic events. M.Dragoni (Istituto di Geofisica, Univ. di Bologna, Bologna, Italy). *M.Gasperini. Riv. Nuovo Cimento (Italy)*, vol.5, ser.3, no.11, p.1-28 (1982). The authors re-propose the method of hypocentre localization based on the evaluation of the azimuth and the angle of emergence of seismic waves. This method is intended to be employed mainly in local networks of seismic stations, where seismicity is studied with greater detail and more accurate determination of earthquake foci are required. Its principal characteristics are analysed and compared with those of currently used methods, based on time measurements only. The basic mathematical theory which is implied is briefly reviewed. Some historical articles and books on the subject are also referenced in the course of the paper. (39 refs.)

78473 Estimating the kinematic parameters of seismic waves by the focusing method. S.V.Gol'din (Inst. of Geology & Geophys., Novosibirsk, USSR). *Sov. Geol. & Geophys. (USA)*, vol.23, no.4, p.65-75 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.4, p.71-80 (1982). If a reversed continuation of the seismic wave field is constructed, with various values of the velocity v_0 in the lower half-space, for certain values of $v_0 = v_{ex}$ the waves identifiable as representing the geometry of the reflecting objects will have the maximum amplitude. In the general case, the extreme velocity v_{ex} is not the same as the true (or effective) velocity in the medium. Formulae are derived relating the extreme velocity to the derivatives of the eikonal of the reflected wave and also to the parameters of the medium. These formulae can be used in solving the reverse kinematic problems. (7 refs.)

78474 Focusing properties of seismological transformations. L.D.Gik (Inst. of Geology & Geophys., Novosibirsk, USSR). *Sov. Geol. & Geophys. (USA)*, vol.23, no.4, p.76-83 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.4, p.81-9 (1982). Conditions of maximum image brightness for an object with a cylindrical reflection surface are investigated for D-transformation and M-transformation, RDR, and according to CDP summation. An expression for the apparent value of seismic velocity when the maximum is present is obtained. In particular, with D-transformations, the apparent value of velocity coincides with the real value only for a point object, while for a flat object it is $\sqrt{2}$ times higher. It has been shown that for the above mentioned types of transformations there is a possibility of false images if the interval of the receiver array exceeds $\lambda/2$ for a CRP observation system, and $\lambda/4$ in central rays. (9 refs.)

78475 On the results of measurements of vibroseismic signals and noise levels in vibro-DSS. V.I.Yushin (Inst. of Geology & Geophys., Novosibirsk, USSR). *Sov. Geol. & Geophys. (USA)*, vol.23, no.4, p.84-8 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.4, p.89-94 (1982). Presents results of absolute measurements of amplitudes of vibroseismic vibrations, generated by a powerful vibration source, at different ranges over a distance of up to 300 km. Also presented are results concerning the level of microseismic noise and the real coefficients of noise stability which were obtained by a correlation method of signal accumulation and signal condensing. Limits of the vibro-DSS method are predicted. (10 refs.)

78476 Algorithm of quick transformation of frequency seismograms into pulse seismograms. G.P.Evchatov (Sci.-Res. Inst. of Geology, Geophys. & Raw Materials, Novosibirsk, USSR). *Sov. Geol. & Geophys. (USA)*, vol.23, no.4, p.97-9 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.4, p.103-6 (1982). An efficient algorithm for the transformation of the phase-distorted frequency response of a geologic medium into a pulse reaction is described. The algorithm is due to a Fourier quick transformation and is intended to be used in the processing of vibroseismic information obtained by the frequency method. (6 refs.)

78477 The West-African craton margin in eastern Senegal: a seismological study. C.Dorbat (Office de la Recherche Sci. et Tech. Outre-Mer, Paris, France), L.Dorbat, A.Le Page, R.Gaulon.

Ann. Geophys. (France), vol.1, no.1, p.25-36 (Jan.-Feb. 1983).

A vertical short period seismological survey was operated for six months in eastern Senegal. Large P-wave travel-time anomalies are in fairly good relation with the gravity and geological features. Two-dimensional inversion of the data shows the existence of a major vertical discontinuity extending from the surface to 150-200 km depth. The other heterogeneities are mainly located in the crust and related to specific segments of the regional geology: craton, Mauritanides and Senegalo-Mauritanian basin. The main discontinuity dipping to the east is interpreted. The authors propose the following geodynamical process to explain the formation of the Mauritanides orogenic belt: continental collision after opening of a back-arc marginal basin in Late Precambrian and its closure until the Devonian. (43 refs.)

78478 Model heat flow and [magnetotellurics] for the San Andreas and oceanic transform faults. Y.Ricard, C.Froidevaux (Lab. de Geophys. et Geodynamique Interne, Univ. de Paris-Sud, Orsay, France), J.F.Hernance.

Ann. Geophys. (France), vol.1, no.1, p.47-52 (Jan.-Feb. 1983).

Two-dimensional temperature structures are computed for a lithospheric shear zone in order to predict the geometry of the hot anomalous region caused by shear heating. The results are compatible with earlier one-dimensional models. The comparison with the heat flow data from California is quite satisfactory. It requires to take into account the geometrical constraints corresponding to the migration of the Medocino triple point (Furlong, 1982). This is obtained by solving the time dependent heat equation. The possibility to probe the existence of a sub-Moho hot window by magnetotelluric sounding is then examined. A drop in apparent resistivity by a factor 2 to 4 is predicted. However, the presence of conductive sedimentary basins at the surface may hide this effect in California. (18 refs.)

78479 A Nd isotope investigation of sediments related to crustal development in the British Isles. R.K.O'Nions, P.J.Hamilton, P.J.Hooker (Dept. of Earth Sci., Cambridge Univ., Cambridge, England).

Earth & Planet. Sci. Lett. (Netherlands), vol.63, no.2, p.229-40 (May 1983).

The times of original fractionation of the Sm and Nd component of clastic sediments from a mantle source (=crustal residence age) have been estimated from Sm-Nd model ages calculated relative to a depleted mantle evolution. In this way the provenance and evolution of selected Precambrian and Phanerozoic sediments and metasediments from the British Isles have been examined. Whereas some Archaean and early Proterozoic sediments have Sm-Nd model

ages that are close to their stratigraphic age, the Phanerozoic sediments analysed have model ages as much as 2.0 Ga in excess of their stratigraphic age. A more detailed study of Lower Palaeozoic sediments deposited on the northern margin of the Iapetus Ocean provides evidence for a marked change of provenance in the Ordovician after the deposition of the Dalradian Supergroup. A component with comparatively high $^{143}\text{Nd}/^{144}\text{Nd}$ and Sm/Nd ratio (presumably basaltic) is present in the sediments throughout the accretionary prism. Crustal residence age estimates average about 1.5 Ga for both these Lower Palaeozoic sediments, and modern pelagic clays, and collectively fail to provide any evidence for significant continental growth during the Phanerozoic. (72 refs.)

78480 Isotopic and trace element constraints on the genesis of the Faeroe lava pile. C.Gariépy, J.Ludden, C.Brooks (Dept. de Géologie, Univ. de Montréal, Montréal, Québec, Canada). *Earth & Planet. Sci. Lett. (Netherlands)*, vol.63, no.2, p.257-72 (May 1983). Basaltic lavas from the Faeroe Islands form three stratigraphic series which define two geochemical groups. Both the lower and middle series are LREE enriched and are characterized by convex LREE profiles; in contrast, the upper series comprises both depleted and enriched lavas. This twofold geochemical division is also evident from the incompatible trace elements such as Zr, Nb, Hf and Ta and the compatible trace elements Cr, Ni, Sr and Y. Nd-Sr-Pb isotopic measurements show that the basalts are contaminated by crustal materials, implying the presence of Precambrian sialic basement underneath the Faeroes block, a conclusion supported by geophysical data. The uncontaminated end-members, for the LREE-depleted basalts and for the LREE-enriched basalts require two different mantle source regions thus posing serious problems for petrogenetic models. The authors interpret the LREE-depleted basalts as partial melts of the oceanic asthenosphere whilst the LREE-enriched basalts may result either from the partial melting of deep mantle blobs or of the subcontinental lithosphere during upwelling of the asthenosphere. (48 refs.)

78481 Sr isotope and trace element evidence for the role of continental crust in calc-alkaline volcanism on Santorini and Milos, Aegean Sea, Greece. M.Barton, V.J.M.Salters, J.P.P.Huijsmans (Dept. of Geochem., State Univ. of Utrecht, Utrecht, Netherlands). *Earth & Planet. Sci. Lett. (Netherlands)*, vol.63, no.2, p.273-91 (May 1983). $^{87}\text{Sr}/^{86}\text{Sr}$, major and trace element data are presented for calc-alkaline lavas from Santorini and Milos islands in the Aegean Sea, Greece. $^{87}\text{Sr}/^{86}\text{Sr}$ ratios of fresh lavas from Santorini range from 0.70472 to 0.70509 whereas those of fresh lavas from Milos lie in the range 0.70540-0.70620. Altered lavas from both islands have higher $^{87}\text{Sr}/^{86}\text{Sr}$ ratios. The range of $^{87}\text{Sr}/^{86}\text{Sr}$ ratios of fresh lavas from Santorini is only just greater than the maximum analytical uncertainty and is thus considered to reflect that of the parental magmas from which the lava series was derived. For the analysed Milos lavas (dacite-rhyolite) there is no correlation between $^{87}\text{Sr}/^{86}\text{Sr}$ and any major or trace element concentration. The relatively high $^{87}\text{Sr}/^{86}\text{Sr}$ ratios of the Santorini and Milos parental magmas indicate that terrigenous material has played a role in their genesis. This could be either via the subduction process or by assimilation of lower crustal material during ascent of mantle-derived magmas. (58 refs.)

78482 Age determinations in the Precambrian basement of the Wadi Araba area, southwest Jordan. G.Jarrar (Dept. of Geology & Mineralogy, Univ. of Jordan, Amman, Jordan), A.Baumann, H.Wachendorf. *Earth & Planet. Sci. Lett. (Netherlands)*, vol.63, no.2, p.292-304 (May 1983). The Precambrian basement of Jordan belongs to the northern margin of the Arabian-Nubian Shield. Age determinations by U-Pb isotopic analyses on sized and magnetic zircon fractions, a monazite and an apatite sample and by Rb-Sr isotopic studies on whole-rocks and minerals of metasedimentary rocks, granodiorites, granites and dykes have elucidated the following events: (1) A major regional high-grade metamorphism accompanied by migmatization and synkinematic plutonism occurred at about 800 Ma. (2) During a postkinematic plutonic event between 615 and 600 Ma extensive masses of granodiorite to granitic composition and dykes were emplaced. (3) A younger plutonic event produced diorites and dykes at about 570 Ma. The plutonic events are related to the Pan-African orogenic phase. The low initial $^{87}\text{Sr}/^{86}\text{Sr}$ ratios of the plutonic rocks correspond to values reported from equivalent rocks throughout the Arabian-Nubian Shield and suggest that no significant portions of ancient sialic crustal material contributed to the generation of the granitic to granodioritic magmas. (33 refs.)

78483 Uranium estimation in Mussoorie phosphorites using solid state nuclear track detector. Surinder Singh, H.S.Virk (Dept. of Phys., Guru Nanak Dev Univ., Amritsar, India). *Indian J. Pure & Appl. Phys.*, vol.21, no.2, p.125-6 (Feb. 1983). A fission track analysis has been used to estimate the uranium concentration in phosphorite deposits of Mussoorie syncline in the lesser Himalayan region of Uttar Pradesh. The uranium content in these deposits has been found to vary from 0.01 to 0.06%. (8 refs.)

78484 Mathematical modeling in the solution of a two-dimensional inverse problem according to deep seismic sounding data. N.I.Pavlenkova, I.Psencik (O.Yu. Schmidt Earth Phys. Inst., Acad. of Sci., USSR). *Izv. Akad. Sci. USSR, Phys. Solid Earth (USA)*, vol.18, no.2 (1982). Translation of: *Izv. Akad. Nauk SSSR Fiz. Zemli*, vol.18, no.2, p.90-7 (1982). The possibilities of mathematical modeling for constructing velocity cross sections of the Earth's crust on the basis of deep seismic sounding data are considered. A brief description is given of the RATLIM program developed for calculating the times and amplitudes of reflected and refracted waves in horizontally inhomogeneous media. In the case of one of the seismic profiles it is shown that mathematical modeling enables one to broaden the class of investigated media and to determine the nature of the main components of the wave field. (28 refs.)

78485 On the thermal effects of groundwater flow. I. Regional scale systems. L.Smith (Dept. of Geological Sci., Univ. of British Columbia, Vancouver, Canada), D.S.Chapman. *J. Geophys. Res. (USA)*, vol.88, no.B1, p.593-608 (10 Jan. 1983). [received: May 1983] Numerical solutions of the equations of fluid flow and heat transport are used to quantify the effects of groundwater flow on the subsurface thermal regime. Simulations are carried out for a vertical section through a basin with a distance of 40 km separating the regional topographic high and low. Emphasis is placed on understanding the conditions under which advective effects significantly perturb the thermal field. The transition from conduction-dominated to advection-dominated thermal regimes is sharp and depends primarily on the topographic configuration of the water table, the magnitude and spatial distribution of permeability, hydraulic anisotropy, and the depth of active flow. Deviations of surface heat flow from the background heat flux are a measurable effect of groundwater flow and depend on the same factors. The results show that from 0% to almost 100% of the section may have surface heat flow significantly different from background heat flow, depending upon the nature of the hydrogeologic environment. (60 refs.)

78486 Heat transfer through the sediments of the mounds hydrothermal area, Galapagos Spreading Center at 86°W. K.Becker (Marine Phys. Lab., Univ. of California, La Jolla, CA, USA), R.P.Von Herzen. *J. Geophys. Res. (USA)*, vol.88, no.B2, p.995-1008 (10 Feb. 1983). Heat transfer processes at the mounds area of the Galapagos Spreading Center at 86°W are revealed by temperatures measured at $\approx 10\text{-m}$ intervals in the 30 $\pm 10\text{ m}$ sediment at each of 12 holes at DSDP Leg 70 Sites 506-509 and by temperatures of up to five thermistors on eleven 8-12 m long piston cores. The 325 needle-probe values show a significant linear increase of thermal conductivity with depth in each core. About half of the temperature-thermal resistance profiles are nonlinear and are fit to a steady state, vertical pore water advection model. Results indicate high and variable total heat flow and localized hydrothermal discharge at $\approx 10^{-8}\text{ m/s}$, associated with individual mounds. Recharge is indicated at similar rates in the low heat flow belt $\approx 5\text{ km}$ south of the mounds and is suggested at slower rates in the intermediate heat flow belt surrounding the mounds heat flow high. Possible slow entrained recharge within $\approx 100\text{ m}$ of discharging mounds is suggested. Also suggested is strong local discharge along the major fault bounding the mounds crustal block to the north. (37 refs.)

78487 Heat transfer and intraplate deformation in the Central Indian Ocean. C.A.Geller, J.K.Weissel, R.N.Anderson (Lamont-Doherty Geological Obs., Columbia Univ., Palisades, NY, USA). *J. Geophys. Res. (USA)*, vol.88, no.B2, p.1018-32 (10 Feb. 1983). Nineteen new heat flow measurements made across deformed oceanic lithosphere in the Central Indian Ocean and previously published data show that heat flow is significantly higher than predicted by models for cooling oceanic lithosphere over much of the region. Many of the temperature-depth profiles are nonlinear. Upward convection of water is the most likely explanation for the curvature of the temperature profiles. This interpretation requires water velocities of the order of $7 \times 10^{-8}\text{ m/s}$, which is unusual because the lithosphere is relatively old (72-82 m.y.) and a thick sedimentary cover (1-2.5 km) is present. These observations suggest that the processes causing deformation of the plate have increased the heat flux through the sediment-water interface. Extra heat is being generated at shallow depths (perhaps less than 35 km) in the plate. (53 refs.)

78488 Numerical models for the hydrothermal field at the Galapagos Spreading Center. U.Fehn (Dept. of Geological Sci., Univ. of Rochester, Rochester, NY, USA), K.E.Green, R.P.Von Herzen, L.M.Cathles. *J. Geophys. Res. (USA)*, vol.88, no.B2, p.1033-48 (10 Feb. 1983). The heat flow distribution at the Galapagos Spreading Center is compared to results of two-dimensional numerical models for the hydrothermal convection through oceanic crust. The model calculations are based on the equations for fluid flow through porous media adapted for the situation at spreading oceanic ridges. The temperature and pressure-dependent thermodynamic characteristics of water were used in the fluid flow equations. Models with average permeabilities of approximately $5 \times 10^{-15}\text{ m}^2$ and penetration depths between 2 and 5 km produce heat flow distributions compatible with the observations at the Galapagos Spreading Center. Because of the convective heat loss, temperatures within the hydrothermal layer are significantly lower than for conductively cooling crust. Two different types of convection cells develop. (41 refs.)

78489 Heat flow on the western flank of the East Pacific Rise at 21°N. K.Becker (Marine Phys. Labs., Univ. of California, San Diego, La Jolla, CA, USA), R.P.Von Herzen. *J. Geophys. Res. (USA)*, vol.88, no.B2, p.1057-66 (10 Feb. 1983). Reports 48 new heat flow measurements on the western flank of the East Pacific Rise at 21°N. The stations were taken in 1 to 30 m of sediment on 0.4 to 1.4 m.y. old crust. The low average measured value of $\approx 173\text{ mW/m}^2$ (including 12 tilted minimum values) is about 1/3 the mean heat flow predicted for crust of this age range by cooling plate theory. This may be partly due to a bias of measurement locations in sediment ponds. Nevertheless, 4-km running averages of measured heat flows, projected normally to the axis, display an oscillatory trend suggestive of cellular hydrothermal circulation in the basement. (47 refs.)

78490 Anomalous heat flow in the northwest Atlantic: a case for continued hydrothermal circulation in 80-m.y. crust. R.W.Embley (Nat. Ocean Survey/NOAA, Rockville, MD, USA), M.A.Hobart, R.N.Anderson, D.Abbott. *J. Geophys. Res. (USA)*, vol.88, no.B2, p.1067-74 (10 Feb. 1983). A detailed study of a $60 \times 150\text{ km}$ area at 60°W, 24°N at the eastern end of the Nares Abyssal Plain indicates that hydrothermal circulation is still active in the 80 m.y. B.P. oceanic crust. The 58 heat flow measurements made at five stations in the area have revealed (1) constant heat flow over the abyssal plain (56 mW m^{-2}), (2) a cyclic heat flow over the abyssal hills (mean of 77 mW m^{-2}), and (3) a large anomaly of 710 mW m^{-2} over one of several small domes which protrude from the abyssal plain. The domes are 0.5-1.0 km in diameter near the top and rise 50 m above the level of the abyssal plain. These features are probably small volcanoes. Overall, the results from the Nares survey vividly show the age independent muting effect of sediment on the surface manifestation of crustal convection. In this survey area the mode of heat transfer varies from purely conductive in the more thickly sedimented abyssal plain areas ($\sim 300\text{ m}$ sediment cover) to moderate amplitude convection pattern beneath the abyssal hills ($\sim 75\text{ m}$ sediment cover) to a very large thermal anomaly over the small dome or 'chimneylike' structure ($\sim 10\text{ m}$ sediment cover). (36 refs.)

78491 Thermal parameters of the oceanic lithosphere estimated from geoid height data. A.Cazenze, B.Lago, K.Dominh (Groupe de Recherche de Géodésie Spatiale, Centre Nat. d'Etudes Spatiales, Toulouse, France). *J. Geophys. Res. (USA)*, vol.88, no.B2, p.1105-18 (10 Feb. 1983). Geoid height anomalies derived from SEASAT altimeter data have been analyzed across fracture zones and over ocean ridges in two limited regions of the South Pacific (Eltanin fracture zone system; East Pacific Rise) and southeast Indian Ocean. Observed geoid height-age and geoid height derivative (with respect to age)-age relationships have been established. Comparison with theoretical relationships computed for the plate model of lithospheric cooling permits an estimation of the thermal parameters entering into the model. Two quantities can be derived: the product $\alpha k T_m$ (α , thermal diffusivity; k , volume coefficient of thermal expansion; T_m , bottom boundary temperature) and the thickness H of the plate. (28 refs.)

78492 A seismic model of a partially molten inner core. D.E.Loper (Geophys. Fluid Dynamics Inst., Florida State Univ., Tallahassee, FL, USA), D.R.Fearn. *J. Geophys. Res. (USA)*, vol.88, no.B2, p.1235-42 (10 Feb. 1983). Fearn et al. (1981) recently proposed a mechanism whereby the inner core contains a significant fraction of liquid. The authors construct a model of a partially molten inner core compatible with seismic observations. Specifically, an improved model of bulk anelasticity is developed including the effect of thermal and material diffusion. It is shown that it is quantitatively capable of explaining the observed anelasticity. Also, studies of the reflection of seismic

waves from the inner-core boundary are used to estimate the mass fraction of liquid in the inner core. (50 refs.)

78493 Isotope geochemistry of Cenozoic volcanic rocks reveals mantle heterogeneity below western USA. M.A.Menzies (Dept. of Earth Sci., Open Univ., Milton Keynes, England), W.P.Leeman, C.J.Hawkesworth. *Nature (GB)*, vol.303, no.5914, p.205-9 (19 May 1983).
Isotope geochemistry of Cenozoic volcanic rocks from the western USA demonstrates considerable mantle heterogeneity in the source regions. The Basin and Range volcanic rocks have tapped a source similar to mid-oceanic ridge basalts and the Hawaiian islands, while the magmas erupted in the Sierran Province formed in enriched grossly heterogeneous garnet bearing mantle. Within the bimodal rhyolite-basalt province of the Snake River Plain and Yellowstone National Park, there exist olivine tholeiites that have retained the primary isotopic characteristics of their mantle source area. (38 refs.)

78494 Uranium enrichment in Archean crustal basement associated with overthrusting. L.M.Lobato, J.M.A.Forman (Nuclebras, Rio de Janeiro, Brazil), W.S.Fyfe, R.Kerrick, R.L.Barnett. *Nature (GB)*, vol.303, no.5914, p.235-7 (19 May 1983).
Uranium deposits cumulatively in the 100000 tonne U_3O_8 range occur within ductile shear zones transecting Archean basement gneisses at Lagoa Real, north-east of Caetite, State of Bahia, Brazil. The authors describe the detailed geology of these deposits and discuss their origin. Limited U-Pb dating of the deposits indicates that U-mineralization occurred at ~820 Myr, involving removal of Si and K coupled with Na addition in oxidizing conditions. V, Pb and light rare-earth elements were introduced along with uranium, from hypersaline CO_2 -hydrocarbon-rich fluids, with $\delta^{18}O-4$ at temperatures of ~540°C, depths of ~15 km, and $P_{fluid} > P_{load}$. It is shown that the geological constraints are consistent with release, through hydrofracturing, of ~1000 km³ of over-pressurized-metamorphic water-recharged formation brines in the Proterozoic sediments up through the hot overlying gneisses. (33 refs.)

78495 Redox state of Earth's upper mantle from kimberlitic ilmenites. S.E.Haggerty, L.A.Tompkins (Dept. of Geology, Univ. of Massachusetts, Amherst, MA, USA). *Nature (GB)*, vol.303, no.5915, p.295-300 (26 May 1983).
Temperatures and oxygen fugacities are reported on discrete ilmenite nodules in kimberlites from West Africa which demonstrate that the source region in the upper mantle is moderately oxidized, consistent with other nodule suites in kimberlites from southern Africa and the United States. A model is presented for a variety of tectonic settings, proposing that the upper mantle is profiled in redox potential, oxidized in the fertile asthenosphere but reduced in the depleted lithosphere. (54 refs.)

78496 A seismological constraint on the depth of basalt-eclogite transition in a subducting oceanic crust. Y.Fukao, S.Hori (Dept. of Earth Sci., Nagoya Univ., Nagoya, Japan), M.Ukawa. *Nature (GB)*, vol.303, no.5916, p.413-15 (2 June 1983).
The oceanic crust primarily has a basaltic composition which must transform into eclogite on subduction of the oceanic crust beneath continents. There has been a considerable debate about the role of the basalt-eclogite transformation in driving lithospheric plate motion and in the thermal regime of subducting plates. How important this transformation is in tectonics critically depends on the depth of transformation, which is affected by factors such as temperature, bulk rock chemical composition, water content and, perhaps, stress environment. Because it would be practically impossible to evaluate all these factors correctly, the authors attempt to constrain the transformation depth by a more direct seismological method. (18 refs.)

78497 Age of the Dashkinskii Formation of the Yenisei Ridge. V.Yu.Shenfil, A.N.Didenko, V.G.Pyatiletov (Inst. of Geology & Geophysics, Acad. of Sci., Novosibirsk, USSR). *Sov. Geol. & Geophys. (USA)*, vol.23, no.3, p.37-45 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.3, p.44-52 (1982).
A complete stratigraphic description of the deposits of the Dashkinskii Formation along the Uderey River is given. Based on finds of plant microfossils, the authors establish its Late Riphean age. The justification for identifying the lower boundary of the Bedomian, or Kudash, according to microfossils is debated. (30 refs.)

78498 The tectonic complex of Baikalian age in the Yakut ASSR. A.K.Basharin, G.S.Gusev, F.F.Tretyakov (Inst. of Geology & Geophysics, Novosibirsk, USSR). *Sov. Geol. & Geophys. (USA)*, vol.23, no.4, p.15-19 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.4, p.19-24 (1982).
Sets forth a basic scheme for the structure of the Baikalian (Lower Proterozoic (?) to Riphean) complex that developed in the east of the Siberian platform and within the Verkhoyan-Kolyma folded region. It is stated that the separation of the Verkhoyan-Kolyma region from the platform did not occur until Middle and Late Riphean time, and that the plate complex within the platform as well as the geosynclinal complex in the Northeastern USSR were formed in the Caledonian stage of tectonic development. 91.40 VOLCANOLOGY

78499 About the existence of two volcanic cycles within the initial volcanism of Virunga (Northern Kivu, Zaire). A.B.Kampunzu (Lab. de Petrologie, Univ. d'Aix-Marseille, Marseille, France), R.T.Lubala, J.P.H.Caron, P.-J.Vellutini. *C.R. Seances Acad. Sci. Ser. II (France)*, vol.296, no.11, p.839-44 (21 March 1983). In French.
Basalts belonging to the olivine tholeiitic series were observed underlaying the alkaline lavas of the initial stage of the Virunga volcanism in the African rift. The different terms of the alkaline series (ankaraites, basanites, hawaïites, mugearites and benmoreites) can be interpreted as the result of a fractional crystallization process. The tholeiitic and sodic alkaline lavas (first and second volcanic cycle) are related to normal faults of the rift and marks the initial fracture stage in this region. They are capped by the potassic and perpotassic alkaline lavas clearly associated with transverse faults of the rift. (19 refs.)

78500 The isotopic and chemical evolution of Mount St. Helens. A.N.Halliday, A.E.Fallick, A.P.Dickin, A.B.Mackenzie (Scottish Univs. Res. & Reactor Centre, Glasgow, Scotland), W.E.Stephens, W.Hildreth. *Earth & Planet. Sci. Lett. (Netherlands)*, vol.63, no.2, p.241-56 (May 1983).
Isotopic and major and trace element analysis of nine samples of eruptive products spanning the history of the Mount St. Helens volcano suggest three different episodes: (1) 40000-25000 years ago: eruptions of dacite with $\epsilon_{Nd} = +5$, $\epsilon_{Sr} = -10$, variable $\delta^{18}O$, $^{206}Pb/^{204}Pb \sim 18.76$, $Ca/Sr \sim 60$, $Rb/Ba \sim 0.1$, $La/Yb \sim 18$, (2) 2500-1000 years ago: eruptions of basalt, andesite and dacite with $\epsilon_{Nd} = +4$ to $+8$, $\epsilon_{Sr} = -7$ to -22 , variable $\delta^{18}O$, $^{206}Pb/^{204}Pb = 18.81-18.87$, variable Ca/Sr , Rb/Ba , La/Yb and high Zr, (3) 1000 years ago to present day: eruptions of andesite and dacite with $\epsilon_{Nd} = +6$, $\epsilon_{Sr} = -13$, $\delta^{18}O \sim 6$ per mille, variable $^{206}Pb/^{204}Pb$, $Ca/Sr \sim 77$, $Rb/Ba \sim 0.1$, $La/Yb \sim 11$. None of the products exhibits Eu anomalies and all are LREE enriched. There is a strong correlation between $^{87}Sr/^{86}Sr$ and differentiation indices. These data are interpreted in terms of a mantle heat source melting young crust bearing zircon and garnet, but not feldspar, followed by intrusion of this crustal reservoir by mantle-derived magma which caused further crustal melting and contaminated the crustal magma system with mafic components. (33 refs.)

Episodic rifting and volcanism at Krafla in north Iceland: growth of large ground fissures along the plate boundary See Entry 78508

91.45 PHYSICS OF PLATE TECTONICS

78501 Hercynian ductile deformation of granites within the Marche fault (French Central Massif): evidence for sinistral transcurrent shearing. P.Choukroune, D.Gapais, P.Matte (Univ. de Rennes, Rennes, France). *C.R. Seances Acad. Sci. Ser. II (France)*, vol.296, no.11, p.859-62 (21 March 1983). In French.

Along the Marche fault, structures and quartz fabric patterns within Hercynian syntectonic granites give evidence of large ductile transcurrent sinistral shearing. On a larger scale, the general geometry of fault pattern reflects a large rotation of bulk principal strain axes along the Hercynian belt between the Armorican Massif and the Central Massif. (13 refs.)

78502 West-American Cordillera structures, east of the Sierra Nevada: geodynamic implications. R.Blanchet, H.de La Tour du Pin, M.Le Vo (GIS Oceanologie et Geodynamique, Brest, France), F.Roure, M.Tardy, A.Villien. *C.R. Seances Acad. Sci. Ser. II (France)*, vol.296, no.11, p.863-8 (21 March 1983). In French.
From the Rocky Mountains foreland to the Sierra Nevada, the structural framework of the West-American Cordillera is hyper-allochthonous. The actual superposition of continental realms formerly severed by marine basins with unknown substratum, originated with eastward shearings, generated by Laramian and Oregonian compressive phases. The 'metamorphic core complexes' are located below the thrusting of Beltia. (12 refs.)

78503 The Kanna Thrust (IZU collision zone, central Japan): evolution of the stress regime at the Eurasian-Philippine Sea plates boundary. P.Huchon (Univ. Pierre et Marie Curie, Paris, France). *C.R. Seances Acad. Sci. Ser. II (France)*, vol.296, no.11, p.869-72 (21 March 1983). In French.
Field analysis of brittle deformation shows that two compressive events occurred during the Quaternary. The first event (NW-SE compression) is related to folding and closing of a deep trough (a subduction trench); the second event (NNE-SSW compression) corresponds to present deformation. Using stratigraphic data, these results show that the collision of Izu with

Central Japan, as a drastic change in the tectonic stress regime, occurred some 300000 years ago. (14 refs.)

78504 Structure of the extremal velocity field of advective tectonic movements. V.L.Novikov (Moscow Power Inst., Moscow, USSR). *Izv. Acad. Sci. USSR. Phys. Solid Earth (USA)*, vol.18, no.3, p.167-71 (1982). Translation of: *Izv. Akad. Nauk SSSR Fiz. Zemli*, vol.18, no.3 (1982).

The instability of a two-layer Newtonian viscous incompressible fluid under density inversion conditions is considered. On the basis of a variational principle of advection, the dependence of the structure of the extremal velocity field on the parameters of the problem is obtained. With allowance for this dependence, an attempt is made to formulate a rule for determining the shape of a moving density discontinuity surface from the known values of the mechanical and geometrical parameters of the problem. (5 refs.)

78505 Temporal variation of the different parameters of the seismotectonic process. A.A.Lukk, I.L.Nersesov (O.Yu. Schmidt Inst. of Phys. of Earth, Acad. of Sci., USSR).

Izv. Acad. Sci. USSR. Phys. Solid Earth (USA), vol.18, no.3, p.172-83 (1982). Translation of: *Izv. Akad. Nauk SSSR Fiz. Zemli*, vol.18, no.3 (1982).

Investigates the temporal variations of the elastic-wave velocities v_p , v_s and v_p/v_s , the ratio v_p/v_s , the mean depth of the earthquake foci in the interval 0-10 km, the number N_d of the earthquakes at depths of 13-40 km and the seismotectonic deformation (strain) parameters μ_M and κ , which govern the stress state and the magnitude of the intensity of the mean mechanism tensor, for the Central Garm region, from 1973 to June 1979. The authors perform a correlation analysis of the time series of the above-listed parameters and stress the need for a review of the existing concepts on the parameters v_p/v_s as an independent source of information, for purposes of elucidating the temporal variations in the development of the seismotectonic process. In comparable time series the authors identify the regular variation, which is common for all the parameters in question. There is a definite regularity in the phase shifts of this variation in the time series of the different parameters. This result is interpreted. (42 refs.)

78506 Nucleation and growth of strike slip faults in granite. P.Segall, D.D.Pollard (US Geological Survey, Menlo Park, CA, USA).

J. Geophys. Res. (USA), vol.88, no.B1, p.555-68 (10 Jan. 1983). [received: May 1983]

Fractures within granodiorite of the central Sierra Nevada, California, were studied to elucidate the mechanics of faulting in crystalline rocks, with emphasis on the nucleation of new fault surfaces and their subsequent propagation and growth. Within the study area the fractures form a single, subparallel array which strikes N50°-70°E and dips steeply to the south. Some of these fractures are identified as joints because displacements across the fracture surfaces exhibit dilation but no slip. The joints are filled with undeformed minerals, including epidote and chlorite. Other fractures are identified as small faults because they display left-lateral strike slip separations of up to 2 m. Slickensides, developed on fault surfaces, plunge 0°-20° to the east. The faults occur parallel to, and in the same outcrop with, the joints. The faults are filled with epidote, chlorite, and quartz, which exhibit textural evidence of shear deformation. These observations indicate that the strike slip faults nucleated on earlier formed, mineral-filled joints. Secondary, dilatational fractures propagated from near the ends of some small faults contemporaneously with the left-lateral slip on the faults. Other features of the faulting process are described. (30 refs.)

78507 Large-scale Quaternary detachments in Ventura basin, southern California. R.S.Yeats (Dept. of Geology, Oregon State Univ., Corvallis, OR, USA).

J. Geophys. Res. (USA), vol.88, no.B1, p.569-83 (10 Jan. 1983). [received: May 1983]

The Ventura basin is an east-north-east trending trough in the California Transverse Ranges which records major Quaternary detachment faulting at three levels. The earliest thrusting occurred along weak siltstone interbeds in a sequence dominated by competent basin-plain turbidite sandstone. Because sedimentation continued during thrusting, the age, rate, and direction of thrusting can be worked out. Faulting began 1.3 m.y. ago and ceased 0.65 m.y. ago. The fault set moved up a 45° ramp and ended as a blind thrust. The ramp had topographic expression on the seafloor affecting marine sedimentation. Following the end of deposition 0.2 m.y. ago, the competent basin-plain turbidites underwent flexural slip folding over an incompetent Miocene sequence dominated by shale. The south flank of the Ventura Avenue anticline tilted at 3.4 $\mu\text{rad/yr}$, the anticlinal crest rose at a rate of 15-16 mm/yr decelerating to 4.3-5.2 mm/yr, and the anticline and an adjacent syncline shortened at a rate of 20 mm/yr. The high rate of folding in the Ventura Avenue oil field is described. Further tectonic aspects of this area are described. (37 refs.)

78508 Episodic rifting and volcanism at Krafla in north Iceland: growth of large ground fissures along the plate boundary. E.Hauksson (Lamont-Doherty Geological Obs., Columbia Univ., Palisades, NY, USA).

J. Geophys. Res. (USA), vol.88, no.B1, p.625-36 (10 Jan. 1983). [received: May 1983]

The rifting of the plate boundary in north Iceland forms new ground fissures and reactivates old ones. Continuous growth of fissures is observed in the crust above a magma chamber beneath the Krafla caldera as it responds to changes in subterranean magma pressure. Rapid episodes of fissure formation and reactivation are observed in conjunction with magma intrusions at depth along the rift zone that constitutes the plate boundary between the North American and Eurasian plates. The Krafla caldera contains several fissures that open during periods of uplift lasting 100 to 300 days and that close incompletely in subsidence episodes lasting several hours to 3 weeks. The author describes further aspects of the rifting and describes in detail events that occurred in AD 1977 and 1980. (23 refs.)

78509 The relationship between surface topography, gravity anomalies, and temperature structure of convection. B.Parsons (Dept. of Earth & Planetary Sci., MIT, Cambridge, MA, USA), S.Daly.

J. Geophys. Res. (USA), vol.88, no.B2, p.1129-44 (10 Feb. 1983).

Normal stresses associated with convection in a fluid layer, whose boundaries can deform, produce topography on those boundaries. When the equations of the motion are linear, integral relations between topography on the boundaries and the temperature structure can be found as a function of wavelength. Expressions of this kind have been derived for the case of convection in a constant viscosity fluid when inertial effects are negligible. The total gravity anomaly is the sum of contributions due to the topography on the two boundaries and to temperature variations within the fluid, and similar integral relations between gravity and the temperature structure can also be derived. At wavelengths large compared to the depth the shape of the kernels in the integrals, particularly that for gravity, is sensitive to the boundary conditions used. The transfer function between gravity and topography is also characteristic of the boundary conditions at long wavelengths. In all the cases con-

sidered, there is a transition between short-and long-wavelength behavior which occurs at wavelengths proportional to the layer depth. If the bottom boundary can deform as well as the upper boundary, the gravity anomaly tends to zero-at long wavelengths as the gravity kernel tends to zero everywhere. (32 refs.)

78510 Constraints on extension of continental lithosphere. P.England (Dept. of Geological Sci., Harvard Univ., Cambridge, MA, USA).

J. Geophys. Res. (USA), vol.88, no.B2, p.1145-52 (10 Feb. 1983).

The extension of the continental lithosphere is considered in terms of the deformation of a thin viscous sheet with a temperature-dependent rheology which is governed primarily by the strength of the upper mantle. The lithosphere is subjected either to a constant strain rate or to a strain rate decreasing with time, corresponding to the stretching of a region of fixed volume with a constant velocity boundary condition. The progress of the extension is influenced by the decrease in strength of the lithosphere, owing to its attenuation, and by an increase in strength resulting from cooling. The relative importance of these two effects is studied. (20 refs.)

78511 Mechanics of fold-and-thrust belts and accretionary wedges. D.Davis (Dept. of Earth & Planetary Sci., MIT, Cambridge, MA, USA), J.Suppe, F.A.Dahlen.

J. Geophys. Res. (USA), vol.88, no.B2, p.1153-72 (10 Feb. 1983).

The overall mechanics of fold-and-thrust belts and accretionary wedges along compressive plate boundaries is considered to be analogous to that of a wedge of soil or snow in front of a moving bulldozer. The material within the wedge deforms until a critical taper is attained, after which it slides stably, continuing to grow at constant taper as additional material is encountered at the toe. The critical taper is the shape for which the wedge is on the verge of failure under horizontal compression everywhere, including the basal décollement. A wedge of less than critical taper will not slide when pushed but will deform internally, steepening its surface slope until the critical taper is attained. Common silicate sediments and rocks in the upper 10-15 km of the crust have pressure-dependent brittle compressive strengths which can be approximately represented by the empirical Coulomb failure criterion, modified to account for the weakening effects of pore fluid pressure. A simple analytical theory that predicts the critical tapers of subaerial and submarine Coulomb wedges is developed and tested. (49 refs.)

78512 A detailed study of the Cobb Offset of the Juan de Fuca Ridge: evolution of a propagating rift. H.P.Johnson, J.L.Karsten, J.R.Delaney (School of Oceanography, Univ. of Washington, Seattle, WA, USA), E.E.Davis, R.G.Currie, R.L.Chase.

J. Geophys. Res. (USA), vol.88, no.B3, p.2297-315 (10 March 1983).

The Cobb Offset on the northern portion of the Juan de Fuca Ridge has been identified as the tip of a northward propagating rift. Map compilations of magnetic and seismic data from four new cruises define the present locus of spreading and volcanism on the two ridge segments abutting the Offset and permit detailed modeling of the recent evolution within this transform zone. (27 refs.)

78513 Kerguelen hotspot source for Rajmahal Traps and Ninetyeast Ridge?. J.J.Mahoney, J.D.MacDougall, G.W.Lugmair (Scripps Instn. of Oceanography, La Jolla, CA, USA), K.Gopalan.

Nature (GB), vol.303, no.5916, p.385-9 (2 June 1982).

The hypothesis that hotspots are the sources of many continental flood basalts is evaluated geochemically for the proposed Rajmahal Traps—Ninetyeast Ridge—Kerguelen hotspot system. It appears that the Kerguelen hotspot did not directly feed Rajmahal magmas, although it may have provided a source of heat for Rajmahal activity. (35 refs.)

78514 Tectonophysical zoning of the juncture of the Aldan Shield and the Stanovoi Highlands according to geodesic measurements. E.E.Fotiadi, N.N.Eisikov, G.V.Bocharov, E.P.Chuprina, D.Ya.Yurenas (Inst. of Geology & Geophysics, Acad. of Sci., Novosibirsk, USSR).

Sov. Geol. & Geophys. (USA), vol.23, no.3, p.1-10 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.3, p.3-15 (1982).

A major plan for tectonophysical zoning is developed which uses geodesic data on horizontal movements of the crust. Based on duplicate measurements of the geodesic network in the juncture zone of the southern Aldan Shield and the Stanovoi Range (1954-1979), zoning was accomplished according to the type of deformation, nature of dilation, and intensity of the variation in form with the establishment of the orientation of the major horizontal deformation axes and directions of maximal displacements. (34 refs.)

78515 Convection under a rapidly moving plate and its appearance in the tectonics of platform areas. S.A.Tychkov (Inst. of Geology & Geophys., Acad. of Sci., Novosibirsk, USSR).

Sov. Geol. & Geophys. (USA), vol.23, no.3, p.11-16 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.3, p.15-23 (1982).

Presents some features of the tectonic development of platform areas in the Phanerozoic which could have formed due to the effects of small-scale thermal convection in the upper mantle on the lithosphere of Africa and Eurasia in the period of extensive movement of these plates. (10 refs.)

91.50 MARINE GEOLOGY AND GEOPHYSICS

78516 Neogene sedimentation and erosion in the Amirante Passage, western Indian Ocean. D.A. Johnson (Dept. of Geology & Geophys., Woods Hole Oceanographic Instn., Woods Hole, MA, USA), M.T. Ledbetter, J.E. Damuth.

Deep-Sea Res. Part A (GB), vol.30, no.2A, p.195-219 (Feb. 1983). Twenty piston cores from the northern Mascarene Basin and Amirante Passage reflect the effects of the Deep Western Boundary Current (DWBC) upon the lithologic and stratigraphic record of the Late Cenozoic. The cores span a depth interval of 3350 to 5200 m, representing the transition zone between modern Northern Atlantic Deep Water (NADW)-Circumpolar Water (CPW) and the underlying Antarctic Bottom Water (AABW). Fluctuations in the intensity of circumpolar flow rather than in the rate of production of NADW may have been the major controlling factor in the Late Tertiary erosional history of the Amirante Passage. (59 refs.)

78517 Pore water chemistry of the mounds hydrothermal field, Galapagos Spreading Center: results from Glomar Challenger piston coring. M.L. Bender (Graduate School of Oceanography, Univ. of Rhode Island, Kingston, RI, USA).

J. Geophys. Res. (USA), vol.88, no.B2, p.1049-56 (10 Feb. 1983). On DSDP Leg 70, Glomar Challenger piston coring hydrothermal MnO₂-encrusted nontronite mounds and adjacent pelagic sediments through to basement. Pore waters were collected by centrifuging, squeezing, and in situ sampling; analyses are presented here for Ca, Mg, Si, NH₃, Mn, and Fe. The results confirm Maris and Bender's (1982) conclusions that hydrothermal solutions enriched in Ca by 1-2 mM and depleted in Mg by ~2 mM are upwelling through the mounds and the surrounding pelagic sediments. Si, NH₃, and Mn²⁺ concentrations generally increase upcore, reflecting addition of products of metabolic reactions to upwelling hydrothermal solutions. Pore water iron concentrations decrease upcore, probably as a result of oxidation and precipitation of upwelling hydrothermal iron. The formation of nontronite involves oxidation of dissolved Fe²⁺. (45 refs.)

78518 Constraints upon water advection in sediments of the Mariana Trough. D.H. Abbott, W. Menke (Dept. of Geological Sci., Columbia Univ., Palisades, NY, USA), R. Morin.

J. Geophys. Res. (USA), vol.88, no.B2, p.1075-93 (10 Feb. 1983). Thermal gradient measurements, consolidation tests, and pore water compositions from the Mariana Trough imply that water is moving through the sediments in areas with less than about 100 m of sediment cover. The maximum advection rates implied by the thermal measurements and consolidation tests may be as high as 10⁻⁵ cm s⁻¹ but are most commonly in the range of 1 to 5 × 10⁻⁶ cm s⁻¹. Theoretical calculations of the effect of the highest advection rates upon carbonate dissolution indicate that dissolution may be impeded or enhanced (depending upon the direction of flow) by a factor of 2 to 5 times the rate for diffusion alone. (35 refs.)

78519 Longshore motion generated on beaches by obliquely incident bores. S.C. Ryrie (School of Maths., Univ. of Bristol, Bristol, England).

J. Fluid Mech. (GB), vol.129, p.193-212 (April 1983). Numerical solutions of the two-dimensional shallow-water equations are found for motion on a sloping beach generated by a single bore and by a periodic succession of bores, both incident at small angles. For the latter, periodic longshore motion can always be found if bottom friction (described by the Chezy law) is included. The timescale of the development of longshore motion is also considered. (21 refs.)

78520 Glacial-Holocene transition in deep-sea sediments: manganese-spike in the east-equatorial Pacific. W.H. Berger, R.C. Finkel, J.S. Killingley (Scripps Instn. of Oceanography, Univ. of California, San Diego, La Jolla, CA, USA), V. Marchig.

Nature (GB), vol.303, no.5914, p.231-3 (19 May 1983). Over large areas of the tropical Pacific, calcareous sediments show one or more dark-coloured manganese-rich layers within the uppermost 40 cm of the record. In the east-equatorial Pacific two layers are strongly developed, with the upper one appearing as a double layer in places. The authors report that the lower layer is centred on the glacial-Holocene boundary. Evidence is presented that shows its origin is tied to a pronounced drop in fertility of the ocean. Such a fertility decrease is implicit in a weakening of east-equatorial upwelling systems. If real, it has important ramifications for the history of oceanic (and atmospheric) chemistry. (39 refs.)

78521 Iron-manganese concretions on the ocean bed. E.S. Bazilevskaya. *Priroda (USSR)*, no.3, p.88-93 (1983). In Russian.

The results obtained from the 28-month voyage of the 'Dmitrii Mendeleev' scientific research vessel in the equatorial zone of the Pacific Ocean to study the iron-manganese concretions are discussed. Particular reference is made to the problem of determining the valence state of the manganese in the concretions and the underlying sediments as well as the problem of determining the mobility or the chemical reactions involving Fe, Cu, Ni, Zn and Co. The mechanism by which the iron-manganese concretions are formed is considered. (1 ref.) L.M.H.

91.60 PHYSICAL PROPERTIES OF ROCKS AND MINERALS

78522 Discussion and supplement to 'The stress state of rock and lining in viscoelastic-plastic rock media'. Wang Tsejun (Station of Water Resources & Electric Power, China), Zhu Weishen.

Acta Mech. Sin. (China), no.1, p.95-101 (1983). In Chinese. This is a discussion of a previous paper, 'The stress state of rock and lining in viscoelastic-plastic rock media' (ref. unobtainable). Formulae are revised to include considerations of the existence of deteriorated plastic region in the rock. The authors provide a method to calculate the proper lining time by taking into account the relative action of rock and lining. It is considered that when the lining rigidity is smaller or when its thickness is very thin, there can be a deteriorated plastic region in the rock. This case can also be calculated. Meanwhile some mistakes are corrected in the original paper. (no refs.)

78523 A computerized database for the mechanical properties of coal. M. Costantino (Lawrence Livermore Nat. Lab., Livermore, CA, USA).

Comput. & Geosci. (GB), vol.9, no.1, p.53-8 (1983). (First Annual Conference on 'The Management, Analysis, and Display of Geoscience Data', Golden, CO, USA, 27-29 Jan. 1982). A relational database containing experimental data for the mechanical properties of US and foreign coals is described. Data on the failure curve (compressive strength), hydrostat, Young's modulus, shear modulus, Poisson's ratio, bulk modulus and compressional and shear wave speeds are included, along with references to the original publications. The database contains approximately 50 references and 5000 data entries. (29 refs.)

78524 TRM, ARM and Isr of two natural magnetites of MD and PSD grain size. R.L. Hartstra (Palaeomagnetic Lab., Utrecht, Netherlands).

Geophys. J. R. Astron. Soc. (GB), vol.73, no.3, p.719-37 (June 1983). TRM, ARM and Isr stabilities with respect to alternating fields and high- and low-temperature treatment are compared for a set of artificial rock specimens. The specimens contain grain-size fractions of a homogeneous natural magnetite and a natural magnetite showing exsolution lamellae. The grain-size fractions are in the PSD-MD range and vary between <5 and 250 μm. The use of ARM instead of TRM to determine palaeointensities is discussed in relation to the results obtained. The results of the study are discussed in terms of a remanence composed of PSD surface moments and MD and PSD bulk moments. (43 refs.)

78525 Piezoelectric fabrics of quartz-bearing rocks and their symmetry properties. A.N. Nikitin, E.I. Parkhomenko (O.Yu. Schmidt Inst. of Phys. of Earth, USSR).

Izv. Acad. Sci. USSR. Phys. Solid Earth (USA), vol.18, no.2 (1982). Translation of: *Izv. Akad. Nauk SSSR Fiz. Zemli*, vol.18, no.2, p.104-10 (1982). It was proved experimentally on specimens of vein quartz that the most reliable determination of the type of symmetry of a piezoelectric fabric of a rock is that based on the property of the nature of the symmetry of the fabric being reflected in the structure of the electric field arising in piezoelectric polarization of a rock specimen. The conditions necessary for determining the order of the axes of symmetry of the piezoelectric fabrics of rocks were found experimentally. Criteria are formulated for the unambiguous determination of the type of symmetry of the piezoelectric fabric of a rock. (9 refs.)

78526 Use of magnetic susceptibility tensor for solving problems in structural geology. V.N. Zavoyskiy (S.I. Subbotin Inst. of Geophys., Acad. of Sci., Ukrainian SSR).

Izv. Acad. Sci. USSR. Phys. Solid Earth (USA), vol.18, no.3, p.217-23 (1982). Translation of: *Izv. Akad. Nauk SSSR Fiz. Zemli*, vol.18, no.3 (1982). Analyzes the relationship between the character of plastic deformation in natural rock outcrops and the eigendirections of the tensor of irreversible magnetic susceptibility, determined on oriented rock samples. It is found that the orientation of the eigendirection corresponding to the maximum eigenvalue of the susceptibility tensor is governed by shearing deformation of the rock. The author gives examples to illustrate the use of measurements of magnetic susceptibility tensor for solving problems concerning the structural geology of different kinds of rocks of the Ukrainian shield. (10 refs.)

78527 Elastic anisotropy in marine sedimentary rocks. R.T. Bachman (Naval Ocean Systems Center, San Diego, CA, USA).

J. Geophys. Res. (USA), vol.88, no.B1, p.539-45 (10 Jan. 1983). [received: May 1983]

Measurements of four of the five elastic stiffnesses of marine calcareous rocks and estimates of the fifth, c_{13} , allow more detailed discussion of elastic wave propagation in these rocks than previously possible. The constant c_{13} , which is seldom measured and was not measured in the rocks of this study, was derived by equating the Gassmann and Hashin-Shtrikman estimates of the bulk moduli of chalk and limestone and then solving for the single unknown c_{13} . On the basis of these measurements and estimates, the effect of elastic anisotropy on seismic reflection determinations of vertical compressional wave speed in calcareous rocks below the Earth's surface is small ($\pm 6\%$), whereas similar determinations of vertically polarized shear wave speeds may be unreliable. Relationships are provided to convert seismic refraction measurements of horizontal compressional wave velocity to vertical velocity. (46 refs.)

78528 Microcrack connectivity in rocks: a renormalization group approach to the critical phenomena of conduction and failure in crystalline rocks. T.R. Madden (Dept. of Earth & Planetary Sci., MIT, Cambridge, MA, USA).

J. Geophys. Res. (USA), vol.88, no.B1, p.585-92 (10 Jan. 1983). [received: May 1983]

A study is made of the critical phenomena associated with the onset of electrical conductivity and the onset of failure in a rock with a random distribution of microcracks using a renormalization group theory approach. The interaction between different length scales is an important element in the theory, which is a departure from the results of equivalent media theory. The crack parameter that determines if the rock can conduct or is to fail is the crack count per unit area times the square of the crack length. The parameter space is divided up into regions or phases. These phases are those of no conduction and no failure, conduction and no failure, and conduction and failure. The predictions of the model agree well with SEM data on the microcrack populations of stressed and unstressed rock samples. The crack densities seen in unstressed Westerly granite fall in the range that predicts conduction but no failure. (17 refs.)

78529 Study of ¹⁸O diffusion in magnesium orthosilicate by nuclear microanalysis. O. Jaoul, B. Houlier (Lab. de Geophys. et Geodynamique Interne, Univ. Paris-Sud, Orsay, France), F. Abel.

J. Geophys. Res. (USA), vol.88, no.B1, p.613-24 (10 Jan. 1983). [received: May 1983] The self-diffusion of ¹⁸O-enriched oxygen in forsterite was determined by measuring the bulk concentration using the nuclear reaction ¹⁸O(p,α)¹⁵N. Important technical improvements led to a more precise determination of the

¹⁸O diffusion profiles. These results indicate that the self-diffusion coefficient D^* is independent of the annealing duration and the oxygen partial pressure. In addition, the D^* values are found to be lower by nearly 1 order of magnitude than those previously published (preexponential factor $D_0 \sim 2.3 \times 10^{-6} \text{ cm}^2/\text{s}$, activation energy, $\sim 70 \text{ kcal/mole}$). (33 refs.)

78530 Domain wall resonance and stability in magnetite. G.M. Smith, R.T. Merrill (Geophys. Program, Univ. of Washington, Seattle, WA, USA). *J. Geophys. Res. (USA)*, vol.88, no.B1, p.637-44 (10 Jan. 1983). [received: May 1983]

An understanding of the factors governing domain wall stability is crucial to any attempt to model remanence in multidomain materials. This paper introduces a technique to the study of multidomain remanence which has not previously seen application in rock magnetism: domain wall resonance (DWR). It is shown that the variation of the DWR spectra with different RF power levels gives useful, and hitherto unavailable, information about the nature of the potentials which govern domain wall motion. In particular, the authors demonstrate that these potentials must rise less rapidly than a harmonic potential, contrary to previous models. The possible mechanisms for domain wall pinning are discussed and it is concluded that the likeliest candidates for pinning sites in the authors' samples, at least, are large nonuniform dislocation arrays. Finally, a possible method for selectively demagnetizing multidomain grains based on DWR techniques is described. (37 refs.)

78531 On the stability of shear cracks and the calculation of compressive strength. J.K. Dienes (Los Alamos Nat. Lab., Los Alamos, NM, USA). *J. Geophys. Res. (USA)*, vol.88, no.B2, p.1173-9 (10 Feb. 1983).

Griffith's 1921 theory of crack stability is extended to account for the frictional energy dissipation associated with interfacial sliding when the crack faces are in contact. This global energy balance approach is essentially different from Griffith's 1924 local theory of compression cracks, which assumes that instability occurs when the stress at any point exceeds the intrinsic strength of the material. An explicit expression for critical crack size in compression is obtained. On the basis of this expression the authors find the most critical crack orientation and define theoretical strength as the critical stress for that orientation. This uniaxial compression strength significantly exceeds the tensile strength. For example, when the coefficient of friction is unity, the ratio of compressive to tensile strength is 8.7, and the crack plane lies at 13° to the loading direction. Following this, the heating due to interfacial sliding is found by a one-dimensional thermoelastic analysis. It is concluded that under normal conditions the stress field acting on the crack faces is only slightly affected by frictional heating, though the temperature rise may be very high, and melting may occur within microseconds. (15 refs.)

78532 The dependence of fracture mechanical and fluid flow properties on fracture roughness and sample size. Y.W. Tsang, P.A. Witherspoon (Lawrence Berkeley Lab., Univ. of California, Berkeley, CA, USA).

J. Geophys. Res. (USA), vol.88, no.B3, p.2359-66 (10 March 1983). A parameter study has been carried out to investigate the interdependence of mechanical and fluid flow properties of fractures with fracture roughness and sample size. A rough fracture can be defined mathematically in terms of its aperture density distribution. Correlations were found between the shapes of the aperture density distribution function and the specific fractures of the stress-strain behavior and fluid flow characteristics. Well-matched fractures had peaked aperture distributions that resulted in very nonlinear stress-strain behaviour. With an increasing degree of mismatching between the top and bottom of a fracture, the aperture density distribution broadened and the nonlinearity of the stress-strain behavior became less accentuated. The different aperture density distributions also gave rise to qualitatively different fluid flow behavior. Findings from this investigation make it possible to estimate the stress-strain and fluid flow behavior when the roughness characteristics of the fracture are known. (7 refs.)

78533 Investigation of internal friction in fused quartz, steel, Plexiglass, and Westerly granite from 0.01 to 1.00 Hertz at 10^{-8} to 10^{-7} strain amplitude. H.-P. Liu, L. Peselnick (US Geological Survey, Menlo Park, CA, USA).

J. Geophys. Res. (USA), vol.88, no.B3, p.2367-79 (10 March 1983). A detailed evaluation on the method of internal friction measurement by the stress-strain hysteresis loop method from 0.01 to 1 Hz at 10^{-8} to 10^{-7} strain amplitude and 23.9°C is presented. The values of Q_s^{-1} (internal friction under uniaxial compression) determined from the relative phase measurements are $|Q_s^{-1} - Q_s^{-1}| < 2.8 \times 10^{-3}$ for the tool steel sample and $|Q_s^{-1} - Q_s^{-1}| < 2.2 \times 10^{-3}$ for the Westerly granite sample, where Q_s^{-1} is the internal friction of the fused quartz stress sensor under uniaxial compression. These values are consistent with those inferred from the relative modulus dispersion data also presented in this paper. The polymethyl methacrylate (PMM, trade name Plexiglass) sample shows high values of internal friction ($Q_s^{-1} \approx 5 \times 10^{-2}$) with strong frequency dependence and with a maximum in Q_s^{-1} at $\approx 0.4 \text{ Hz}$. (23 refs.)

78534 Deformation of single-crystal clinopyroxenes. II. Dislocation-controlled flow processes in Hedenbergite. J.J. Kolle, J.D. Blacic (Los Alamos Sci. Lab., Los Alamos, NM, USA).

J. Geophys. Res. (USA), vol.88, no.B3, p.2381-93 (10 March 1983). For pt.1 see *ibid.*, vol.87, no.B5, p.4019-34 (1982). Laboratory deformation experiments were carried out on two single-crystal clinopyroxenes: chrome diopside and hedenbergite. The tests were made in a Griggs solid-medium, triaxial, and creep tester. A confining pressure of 1000 MPa was applied in all the experiments. The crystals were deformed at strain rates from 10^{-4} s^{-1} to 10^{-8} s^{-1} and at temperatures from 400°C to 1200°C . Two orientations of the crystals with respect to the maximum principal compressive stress were tested. The authors present results of experiments on (mainly) hedenbergite oriented such that twinning is not possible and deformation occurs by a dislocation-controlled flow process. Empirical flow laws for hedenbergite are presented and contrasted with the twinning results. (18 refs.)

78535 Electrical conductivity of molten basalt and andesite to 25 kilobars pressure: geophysical significance and implications for charge transport and melt structure. J.A. Tyburczy, H.S. Waff (Dept. of Geology, Univ. of Oregon, Eugene, OR, USA).

J. Geophys. Res. (USA), vol.88, no.B3, p.2413-30 (10 March 1983). Electrical conductivities of molten Hawaiian tholeiite and Crater Lake andesite were measured between 1200°C and 1400°C at atmospheric pressure and at pressures up to 17 and 25 kbar, respectively. Isobaric plots of $\log \sigma$ versus $1/T$ (σ is electrical conductivity) are linear, with the exception of the zero pressure tholeiite melt data. Conductivities decrease with increasing pressure in both melts, with the andesitic melt exhibiting a greater pressure dependence. Between 5 and 10 kbar, abrupt decreases in the slopes of isothermal $\log \sigma$ versus P plots (i.e. decreases in activation volume) are observed for both rock melts. This discontinuity probably reflects changes in melt structure, as opposed to changes in conduction mechanism. A qualitative model involving depolymerization of the melt with increased pressure leading to increased efficiency of packing can explain the observed discontinuity in activation volume as well as the observed pressure dependences of other melt physical properties such as viscosity and density. (89 refs.)

78536 Shock temperatures of SiO_2 and their geophysical implications. G.A. Lyzenga, T.J. Ahrens (Seismological Lab., California Inst. of Technol., Pasadena, CA, USA), A.C. Mitchell.

J. Geophys. Res. (USA), vol.88, no.B3, p.2431-44 (10 March 1983). The temperature of SiO_2 in high-pressure shock states has been measured for samples of single-crystal α -quartz and fused quartz. Pressures between 60 and 140 GPa have been studied using projectile impact and optical pyrometry techniques. Both data sets indicate the occurrence of a shock-induced phase transformation at ~ 70 and $\sim 50 \text{ GPa}$ along the α - and fused quartz Hugoniot, respectively. The suggested identification of this transformation is the melting of shock-synthesized stishovite, with the onset of melting delayed by metastable superheating of the crystalline phase. Some evidence for this transition in conventional shock wave equation of state data is given, and when these data are combined with the shock temperature data, it is possible to construct the stishovite-liquid phase boundaries. The melting temperature of stishovite near 70 GPa pressure is found to be 4500K . (29 refs.)

78537 Nuclear magnetic resonance of silica polymorphs. J.V. Smith (Dept. of the Geophys. Sci., Univ. of Chicago, Chicago, IL, USA), C. Scott Blackwell.

Nature (GB), vol.303, no.5914, p.223-5 (19 May 1983). The chemical bonding in silica polymorphs and silicates can be studied by both experimental and theoretical methods. Spinning at the octahedral (magic) angle yields sharp peaks in the NMR patterns for ^{29}Si and ^{27}Al . The authors report magic angle spinning (MAS) spectra for seven polymorphs of silica and interpret the chemical shifts empirically in terms of interatomic distances and angles determined by X-ray diffraction. The conclusions provide a partial basis for quantitative interpretation of spectra for framework aluminosilicates, especially zeolite molecular sieves; additional effects from aluminium substitution and nonframework atoms will need to be evaluated. (29 refs.)

78538 Olivine to spinel transformation in Mg_2SiO_4 via faulted structures. J.N. Boland (Inst. of Earth Sci., State Univ. of Utrecht, Utrecht, Netherlands), Lin-gun Liu.

Nature (GB), vol.303, no.5914, p.233-5 (19 May 1983). The authors report the results of transmission electron microscopy of the $\alpha \rightarrow \gamma$ high-pressure transformation in the pure end-member olivine, forsterite (Mg_2SiO_4). Not only is there a special orientation relationship between the two phases during the transformation, that is, $(100)_{\text{OI}}$ is parallel to $(111)_{\text{SP}}$ and $[001]_{\text{OI}}$ parallel to $[110]_{\text{SP}}$, but some of the residual olivine grains have an extremely high density of stacking faults in $(100)_{\text{OI}}$ as well as a high dislocation density. (14 refs.)

78539 Diagenesis of magnetic minerals in Recent hemipelagic sediments. R. Karlin, S. Levi (School of Oceanography, Oregon State Univ., Corvallis, OR, USA).

Nature (GB), vol.303, no.5915, p.327-30 (26 May 1983). Rapidly deposited sediments from marine and lake environments are being used increasingly to study decadal to millennial fluctuations in the Earth's magnetic field. The objectives are to gain more fundamental understanding of the geodynamo and to establish a new dating technique for sediments. The authors report downcore magnetic profiles from undisturbed Kasten cores taken in rapidly deposited laminated sediments from the Gulf of California and in bioturbated hemipelagic muds on the Oregon continental slope which give apparently reliable directions, but show dramatic decreases in the intensities of natural and artificial remanences with depth. (16 refs.)

78540 Thermal behavior of fine-grained soils. L.A. Salomone, W.D. Kovacs, H. Wechsler.

Report NBS-BSS-149, Nat. Bur. Stand., Washington, DC, USA (Nov. 1982), xii+91 pp.

Laboratory thermal probe tests performed on an AASHTO standard reference material (a silty clay) showed that thermal resistivity ($^\circ\text{C}\cdot\text{cm}/\text{watt}$) varies with soil moisture content and dry density. The tests were performed to correlate soil thermal behavior with the limit states of fine-grained soils. Over 80 thermal resistivity measurements were made on specimens compacted to various densities and moisture contents. (27 refs.)

78541 Microwave emissions from soils with rough surfaces. L. Tsang (Electrical Engng. Dept., Texas A&M Univ., College Station, TX, USA), R.W. Newton.

J. Geophys. Res. (USA), vol.87, no.C11, p.9017-24 (20 Oct. 1982). [received: May 1983]

The effect of surface roughness on the thermal microwave emission of soils has been studied with the Kirchhoff approach. A model is presented that includes both the coherent and incoherent reflectivities of the rough surface. It is demonstrated that both the coherent and incoherent terms must be included in order for theoretical computations to provide good agreement with the experimental data, especially for wet soil, where surface roughness causes a dramatic increase in brightness temperature. In addition, the model including both the coherent and incoherent terms allows one to use the physically measured surface height deviations of the rough surface in the model. Previous models have required that an effective height, not equal to the actual surface height measurements, be used in order for theoretical computations to match measurements. (25 refs.)

78542 Dual nature of ignimbrites. N.V. Koronovskii.

Priroda (USSR), no.3, p.12-18 (1983). In Russian. The special characteristics of ignimbrites, acidic volcanic rocks consisting of volcanic glass and mineral phenocrysts such as quartz, feldspar and pyroxenes, are examined, in particular their dual nature as lavas and brecciated (pyroclastic) volcanogenic rocks. The history of the study of ignimbrites is traced. The acidic volcanic rocks are analysed and divided into two groups—those characterised by extremely small volumes and comprising short lava flows, extruded domes and subvolcanic massifs and those characterised by striation and elongated lens-shaped inhomogeneities. The nature and origins of inhomogeneities in the glass of ignimbrites are discussed as well as the viscosity of acidic ignimbrite melts. From the analysis of the nature of ignim-

brites, a mechanism is postulated for the formation of the lava ignimbrites. (3 refs.) L.M.H.

78543 Isotope composition of lead ore of some fields of the Sayan-Baikal region. N.V.Vilor, N.N.Fefelov, V.N.Solodiyankina, S.B.Brandt (Inst. of Earth's Crust, Acad. of Sci., Irkutsk, USSR). *Sov. Geol. & Geophys. (USA)*, vol.23, no.3, p.57-61 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.3, p.65-70 (1982). Discusses lead isotope studies of lead ore in some gold ore and polymetal fields of the folded framework of the Siberian Platform. Interpretation of isotope data is proposed in terms of a two-stage model, according to which the formation of the ore field in the Sayan-Baikal folded belt could be connected with two major tectonic-magmatic cycles: Middle Proterozoic (1750 ± 75 million years) and Caledonian (460 million years). (19 refs.)

78544 Thermophysical properties of the basic varieties of rocks in the Irkutsk amphitheater. R.P.Dorofeeva (Inst. of Earth's Crust, Irkutsk, USSR). *Sov. Geol. & Geophys. (USA)*, vol.23, no.4, p.103-5 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.4, p.113-15 (1982). Results of an experimental determination of thermal parameters of rocks in the sedimentary cover and the crystalline basement of the Irkutsk amphitheater are discussed. Histograms of the distribution of the coefficients of thermal and temperature conductivity and rock density are constructed. (2 refs.)

78545 Modelling of flow phenomena in porous media. L.Balla (Petroleum Engng. Res. Lab., Hungarian Acad. of Sci., Budapest, Hungary). *Acta Geod. Geophys. & Montan. (Hungary)*, vol.17, no.3-4, p.317-28 (1982). The modelling of flow phenomena in porous media is dealt with. Based on mathematical correlations of the flow, the scaling criteria are described and their suitability for practical use is analyzed. The scaling criteria derived require that the porous structure of the model and that of the prototype should be the same. Further investigations are, however, needed to reproduce the porous structure of the prototype in the model because the parameters characterizing the porous structure are theoretically not yet defined unambiguously and there is no exact measurement method available. Further investigations are required to decide whether the permeability and exponent of the capillary pressure function can unambiguously characterize the porous structure from the point of view of fluid mechanics, or some further parameters have to be defined. If the parameters characterizing the porous structure are unambiguously defined, the next task is to analyse the effect of these parameters on the relative permeability and the wettability, and to express mathematically these relationships. Knowing the parameters characterizing the porous structure and their effect on other parameters influencing the flow, the mathematical model of the flow can be modified. (12 refs.)

78546 Vibration effect and its influence on exogenous geological processes. B.P.Agaonov (Inst. of Earth's Crust, Irkutsk, USSR). *Sov. Geol. & Geophys. (USA)*, vol.23, no.4, p.89-96 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.4, p.95-103 (1982). Reveals some perspectives on the study of exogenous geological processes from the point of view of the influence of natural and technogenic vibration sources on the development of these processes. The influence of vibration sources manifests itself both in slow, imperceptible microshifts of soils and in local stripping movements. Four morphological varieties of stripping are distinguished. Torrents and avalanches are regarded as factors of their own vibration generation, and therefore, of their own self-development. Questions are broached which concern the creation of rock slides and the separation of particles of heavy minerals under the influence of vibration forces. (15 refs.)

78547 Lightning craters. S.Campbell. *Weather (GB)*, vol.38, no.4, p.106-9 (April 1983). Discusses the origin of several craters found at Monynut Edge (1963, July), East Lotherian. The author discusses various possibilities and concludes that they were formed due to lightning. (9 refs.)

78548 The kinematics of a stochastic field of internal waves modified by a mean shear current. H.Peters (Inst. für Meereskunde, Kiel, Germany). *Deep-Sea Res. Part A (GB)*, vol.30, no.2A, p.119-48 (Feb. 1983). Modes and dispersion curves of high-frequency internal waves are calculated from observed profiles of the Brunt-Vaisala frequency and of the mean shear current. Cases treated are from the tropical Atlantic (GATE) and from the North Atlantic (JASIN). The dispersion characteristics are anisotropic. The feature increases in importance with increasing frequency, wavenumber, and mode number. The mean shear strongly deforms the eigenfunctions for modes 2 and higher at upstream wave directions, and separated wave guides occur at different depths. The higher the mode number, the more effective is the critical-layer absorption. By means of the stochastic superposition of shear modes a model of the kinematics of a field of free, linear internal waves is constructed for the GATE situation. (21 refs.)

78549 The translation of isolated cold eddies on a sloping bottom. D.Nof (Dept. of Oceanography, Florida State Univ., Tallahassee, FL, USA). *Deep-Sea Res. Part A (GB)*, vol.30, no.2A, p.171-82 (Feb. 1983). A two-layer analytical model is considered to examine the dynamics of cold isolated patches on the ocean floor. Such patches have been observed in the North Atlantic Ocean and are characterized by a bounding interface that intersects the bottom along a closed curve. They correspond, therefore, to isolated anticyclonic eddies with a lens-like cross section. The model incorporates steady movements resulting from the swirl velocity within the eddy and a topographically-induced translation. For steady motions, analytical solutions are obtained using the full equations of motion in a coordinate system moving with the eddy itself. (18 refs.)

78550 Upwelling along the 60-m isobath from Cape Canaveral to Cape Hatteras and its relationship to fish distribution. L.P.Atkinson, T.E.Targett (Skidaway Inst. of Oceanography, Savannah, GA, USA). *Deep-Sea Res. Part A (GB)*, vol.30, no.2A, p.221-6 (Feb. 1983). During a cruise north in the Gulf Stream from Cape Canaveral to Cape Hatteras several zones of upwelling were observed. Acoustic measurements suggested that fish aggregations were associated with areas of upwelling. Surface salinity and alongshore velocity observations suggest an offshore flow of shelf water in the 32 to 33°N area. (26 refs.)

78551 On perturbations of harmonic constants in the Thames Estuary. M.Amin (Inst. of Oceanographic Sci., Bidston Obs., Birkenhead, England). *Geophys. J. R. Astron. Soc. (GB)*, vol.73, no.3, p.587-603 (June 1983). A long series of South-east sea-level observations (1929-79) is analysed using the harmonic method of tidal analysis. This method introduces a systematic error in tidal analysis and prediction. It is observed that small secular trends are present in amplitudes and phase lags of some principal tidal constituents. The influence of these secular trends in amplitudes is to increase the tidal range and extreme levels. A comparison of old records with tides synthesized by modern constituents for London Bridge suggests that the phase of the tide was almost stable there from 1683 to 1835; then a large change occurred after 1835. Similar changes are noted in the tidal range. The nature of these changes is discussed. (16 refs.)

78552 Experiments on solitary internal Kelvin waves. T.Maxworthy (Dept. of Mech. & Aerospace Engng., Univ. of Southern California, Los Angeles, CA, USA).

J. Fluid Mech. (GB), vol.129, p.365-83 (April 1983). Elementary calculations indicate that the effect of the Earth's rotation is likely to be important in the dynamics of most internal waves in oceans, lakes and the atmosphere. The author presents measurements of the structure and properties of one class of such waves, namely solitary internal Kelvin waves, in which the Coriolis force generated by wave motion in a stratified fluid is opposed by a pressure gradient and hence change in wave amplitude along its crest. The author confirms that the wave speed is independent of the rate at which the system rotates and depends only on the stratification and maximum wave amplitude. However, rotation is shown to have a large effect on both the rate at which the amplitude varies with time and the 'cross-stream' structure of the wave. In accordance with well-established theory, the amplitude transverse to the direction of propagation varies exponentially. This results in a decreasing wave speed with increasing distance from the wall, which in turn requires the wave front to be curved backwards in order for the wave as a whole to propagate at a speed given by its maximum amplitude. Such a front curvature is not contained within the available theories. (29 refs.)

78553 Barge motions in random seas—a comparison of theory and experiment. D.T.Brown, R.Eatock Taylor, M.H.Patel (Dept. of Mech. Engng., London Centre for Marine Technol., Univ. Coll. London, London, England). *J. Fluid Mech. (GB)*, vol.129, p.385-407 (April 1983).

Describes a comparison of experimental data and theoretical results for the motions in waves of large flat-bottomed barges having zero forward speed. The experimental data are derived from model tests at two scales (1:36 and 1:108). These consist of measurements of motions in surge, sway, heave, roll, pitch and yaw to long-crested seas approaching the barge models at two orientation angles (head and beam seas). The experimental data are compared with results computed from linearized potential-flow theory, which accounts for the diffraction and radiation of gravity waves around the barge. The boundary-integral scheme employed to solve this potential-flow problem is briefly reviewed. The experimental data at two scales and the theoretical results show that potential-flow theory is in reasonable agreement with experimental data for all motions except roll near resonance. These roll-motion discrepancies, due to vortex shedding from bilge-keel edges, are discussed. Some of the observable effects of scale in the model tests are highlighted. (11 refs.)

78554 An advective solution of a zonally uniform thermocline regime. P.F.Hodnett (Dept. of Appl. Math., Nat. Inst. for Higher Education, Limerick, Ireland). *Proc. R. Ir. Acad. Sect. A (Ireland)*, vol.82A, no.2, p.187-99 (Dec. 1982). [received: May 1983]

The thermocline region of a large ocean is driven by a surface wind stress and a surface temperature which are independent of longitude. An advective solution is derived where motion takes place under geostrophic and hydrostatic balance and heat is transferred by convection only. Proper account is taken of the Earth's spherical geometry. It is found that the advective solution can satisfy all the boundary conditions, i.e. (i) the bottom velocity condition, (ii) the surface velocity condition and (iii) the surface temperature

condition, contrary to the conclusions of Needer (1971), when considering thermocline models with arbitrary barotropic flow. (10 refs.)

78555 Breaking waves on beaches. D.H.Peregrine (School of Math., Univ. of Bristol, Bristol, England).

In book: *Annual review of fluid mechanics. Vol.15*, M.Van Dyke, J.V.Wehausen, J.L.Lumley [Ed.], p.149-78. Palo Alto, CA, USA: Annual Reviews (1983), 534 pp. [0 8243 0715 1]

Visitors to any coastline exposed to open water can see the dramatic transformation of surface waves that occurs as they advance onto a beach. The waves offshore have a relatively smooth water surface, whereas the waves arriving at the shoreline have rough white fronts of spray and bubbles. The transition between these two types of waves is the subject of this review: the term 'wave breaking' is used to describe the transition from a smooth wave to the quasi-steady state with a white-water front rather than to any particular instant within the transition. (110 refs.)

78556 The form and dynamics of Langmuir circulations. S.Leibovich (Sibley School of Mech. & Aerospace Engng., Cornell Univ., Ithaca, NY, USA).

In book: *Annual review of fluid mechanics. Vol.15*, M.Van Dyke, J.V.Wehausen, J.L.Lumley [Ed.], p.391-427. Palo Alto, CA, USA: Annual Reviews (1983), 534 pp. [0 8243 0715 1]

Many mechanisms for Langmuir circulations have been proposed since Langmuir first reported his observations. Most of these easily can be shown to be nonessential to the phenomenon, and have therefore been dismissed. These early ideas are briefly mentioned, followed by theories not so easily discounted, although serious objections can also be raised about some members of this latter group. Before reviewing the theories, the author gives a sketch of the phenomenon these theories must explain. (81 refs.)

92.20 INTERDISCIPLINARY ASPECTS OF OCEANOGRAPHY

78557 Transport and deposition of plutonium in the ocean: evidence from Gulf of Mexico sediments. M.R.Scott, P.F.Salter (Dept. of Oceanography, Texas A&M Univ., College Station, TX, USA), J.E.Halverson.

Earth & Planet. Sci. Lett. (Netherlands), vol.63, no.2, p.202-22 (May 1983).

A study of sediments in the Gulf of Mexico shows dramatic gradients in Pu content and isotope ratios from the continental shelf to the Sigsbee Abyssal Plain. In terms of predicted direct fallout inventory of Pu, one shelf core contains 745% of the predicted inventory, while abyssal plain sediments contain only 15-20% of the predicted value. Absolute Pu concentrations of shelf sediments are also conspicuously high, up to 110 dpm/kg, compared to 13.5 dpm/kg in Mississippi River suspended sediment. There is no evidence of Pu remobilization in Gulf of Mexico shelf sediments, based on comparison of Pu profiles with Mn/Al and Fe/Al profiles. Horizontal transport of fallout nuclides from the open ocean to removal sites in ocean margin sediments is concluded to be the source of both the high concentrations and high inventories of Pu reported here. (60 refs.)

78558 Preliminary observations on californium-252 behaviour in sea water, sediments and zooplankton. S.R.Aston, S.W.Fowler (Internat. Lab. of Marine Radioactivity, Musee Oceanographique, MC, Monaco).

Health Phys. (GB), vol.44, no.4, p.359-65 (April 1983).

Reports radiotracer experiments on the behaviour of ^{252}Cf in the marine environment. The particulate fraction of californium in sea water approached 45% after four days. Californium rapidly adsorbed onto marine coastal and deep-sea sediments with Kd values from 1.4×10^4 to $\geq 1 \times 10^5$. The concentration of ^{252}Cf in euphausiids reached near-equilibrium factors of 3×10^2 in water after one week; in contrast, the assimilation from food was very low. Excreted pellet pellets, molts and zooplankton carcasses are potentially important vectors for californium re-distribution in the oceans. (15 refs.)

78559 On the radiocarbon record in banded corals: exchange parameters and net transport of $^{14}\text{C}_2$ between atmosphere and surface ocean. E.M.Druffel (Chem. Dept., Woods Hole Oceanographic Inst., Woods Hole, MA, USA), H.E.Suess.

J. Geophys. Res. (USA), vol.88, no.C2, p.1271-80 (20 Feb. 1983). (Symposium on the Rise in Atmospheric Carbon Dioxide, Bern, Switzerland, 14-18 Sept. 1981).

Radiocarbon measurements of banded hermatypic corals from Florida, Belize, and the Galapagos Islands have been made. Interpretation is presented here of these previously reported results. These measurements represent the $^{14}\text{C}/^{12}\text{C}$ ratios in dissolved inorganic carbon (DIOC) in the surface ocean waters of the Gulf Stream and the Peru Current at the time of coral ring formation. A depletion in radiocarbon concentration was observed in corals that grew from A.D. 1900-1952. It was caused by dilution of existing ^{14}C levels with dead CO_2 from fossil fuel burning (the Suess effect, or S_{eff}). The observed depletion of radiocarbon was greater in corals from the Gulf Stream (-11%) than in corals from the Peru Current (-6%). A similar trend was observed in the distribution of bomb-produced ^{14}C in corals that had grown during the years following A.D. 1952. The authors discuss the implications these observations have on vertical mixing and circulation in the ocean. (40 refs.)

78560 Trace metal fronts in European shelf waters. K.Kremling (Inst. für Meereskunde, Kiel, Germany).

Nature (GB), vol.303, no.5914, p.225-7 (19 May 1983).

The Hebrides shelf edge area is characterized by strong horizontal salinity gradients (fronts) which mark the boundary between Scottish coastal and oceanic waters. The results presented here, obtained in summer 1981 on a

transect between the open North Atlantic and the German Bight, confirm that the hydrographical front is accompanied by dramatic increases in inorganic nutrients (phosphate, silicate) and dissolved trace elements such as Cd, Cu, Mn, and ^{226}Ra . These data (together with measurements from North Sea regions) suggest that the trace metals are mobilized from partly reduced (organic-rich) sediments and vertically mixed into the surface waters. The regional variations evident from the transect are interpreted as being the result of the hydrography prevailing in waters around the British Isles. (22 refs.)

78561 Large particle transport of plutonium and other fallout radionuclides to the deep ocean. H.D.Livingston, R.F.Anderson (Dept. of Chem., Woods Hole Oceanographic Inst., Woods Hole, MA, USA).

Nature (GB), vol.303, no.5914, p.228-31 (19 May 1983).

Artificial radionuclides introduced to the atmosphere as a consequence of atmospheric nuclear weapons tests have been detected in deep sediments of the Atlantic and Pacific Oceans. The nuclides which have been found in these sediments have half lives long enough to be detectable 10 or more years after their introduction to the ocean and biogeochemistries which permit particle association and transport. They include such nuclides as $^{239,240}\text{Pu}$, ^{238}Pu , ^{241}Am , ^{59}Fe and ^{137}Cs . For fallout nuclides to have been transported to the deep ocean in the two to three decades since they were delivered to the sea surface, relatively rapid transport through the water column is required. The authors describe the results of radiochemical analyses of Pu and other fallout nuclides in three series of sediment trap samples collected as part of the PARFLUX program. The data are used to consider the role that large particles have in processes which transfer particle reactive artificial radionuclides through oceanic water columns. (33 refs.)

78562 Salinity of sea water. O.I.Mamaev.

Priroda (USSR), no.3, p.19-23 (1983). In Russian.

The problem of determining an absolute value for the salinity of the sea is considered and an attempt is made to find an indirect method of determining salinity rapidly. Previously devised formulae and methods of determining salinity are examined and progress to date in the search for the absolute expression is traced. A new scale is described which yields a value designated as the 'practical' salinity. (3 refs.) L.M.H.

78563 The transient flow in naturally fractured reservoirs with three-porosity systems. Wu Yushu (Sci. Res. Inst. of Petroleum Exploration & Dev., China), Ge Jiali.

Acta Mech. Sin. (China), no.1, p.81-5 (1983). In Chinese.

Presents analytical solutions for the three-porosity model of naturally fractured reservoirs in both infinite and finite systems by using the Laplace transform and the finite Hankel transform, and discusses the general behaviour of this model. In addition, the pressure-drawdown and buildup equations are given for engineering applications. (5 refs.)

78564 Alluvions washing experiment and other difficulties at the hydro-power plants intakes on the Olt river during the May 1981 floodings. S.Cerchez.

Energetica (Romania), vol.30, no.12, p.582-6 (Dec. 1982). In Rumanian.

[received: May 1983]

An experiment for washing away alluvions for a storage lake on the Olt river during a 1500 m³/s flood and the energetic and economic aspects of this operation are presented. The difficulties of fighting the effects of river alluvions during flooding periods are referred to and the components of the relationship of erosion-deposits-energetic effects are appreciated. (7 refs.)

78565 Aero-diffusion method of estimating evaporation in a non-stratified atmosphere. H.S.Takhar, M.W.Liddament (Simon Engng. Labs., Univ. of Manchester, Manchester, England).

Indian J. Pure & Appl. Math., vol.14, no.3, p.412-25 (March 1983).

Experimental observations from four sites are used to verify the aero-diffusion approach (Takhar 1972) to evaporation estimation. Climatological and evaporation data from two of the sites were taken from the published results of Rowher (1931) and the Lake Hefner Base Data Report (1954). The remaining experiments were performed at the Stocks Reservoir, Yorkshire, where meteorological data recorded from an automatic recording station positioned over the water surface were used to compare evaporation estimates given by the aero-diffusion method with those given by the Penman (1948) method,

and at a site near Arley, Cheshire, where the aero-diffusion estimates were compared with the direct measurements from a nine metre diameter, water tight evaporation pool. The results of these experimental studies showed that there was generally good agreement between the water budget estimates and the aero-diffusion estimation of evaporation. (10 refs.)

78566 Porosity and hydraulic properties of sediments from the Galapagos Spreading Center and their relation to hydrothermal circulation in the oceanic crust. S.Karato (Ocean Res. Inst., Univ. of Tokyo, Tokyo, Japan), K.Becker. *J. Geophys. Res. (USA)*, vol.88, no.B2, p.1009-17 (10 Feb. 1983). Density and porosity of sediments were measured on DSDP legs 69 and 70 samples from the Galapagos spreading center. Permeability and the hydraulic impedance of each sediment layer were estimated from measured values of porosity. The gradients of porosity and density with depth where sediment layers are thin (≤ 50 m thick) are anomalously high compared with those of other areas and with the upper part of thicker sediment layers in this area. A good correlation was found between the anomalous porosity and density gradients and the present-day heat flow. These observations suggest that these high gradients may be due to active hydrothermal circulation through a thin sediment cover, which is inhibited by a thicker sediment layer, and that the pattern of hydrothermal circulation may be essentially fixed with the moving plate. Hydraulic impedance of the sediment layer was estimated from the observed depth variation of porosity and was shown to increase rapidly with its thickness. (26 refs.)

78567 On the terrestrial heat flow and physical limnology of Crater Lake, Oregon. D.L.Williams (US Geological Survey, Denver, CO, USA), R.P.Von Herzen.

J. Geophys. Res. (USA), vol.88, no.B2, p.1094-104 (10 Feb. 1983). The heat flow into 7000-year-old Crater Lake caldera is dominated by hydrothermal processes. The average of the conducted heat flow value is 138 ± 121 mW/m² (3.3 ± 2.9 HFU). The total heat flow is estimated to be between 669 and 1381 mW/m² (16 and 33 HFU). Hydrothermal fluids penetrate into the lake floor to a depth of at least 1.5 to 2.0 km and possibly much deeper. Two thermal spring areas were discovered on the deep lake floor. These springs, and probably others as yet undiscovered, have a dramatic effect on the water temperature, circulation, and stratification of the lake. Dense thermal waters pond in the southwest basin. The deep waters of the east and northwest basin are warmed to the point that they convect, causing the lake to be vertically mixed. (40 refs.)

78568 Transport of radon in flowing boreholes at Stripa, Sweden. P.H.Nelson, R.Rachiele, A.Smith (Lawrence Berkeley Lab., Berkeley, CA, USA).

J. Geophys. Res. (USA), vol.88, no.B3, p.2395-405 (10 March 1983). Granitic rock in an underground experimental waste storage site at Stripa, Sweden, is unusually high in natural radioelements (~40 ppm uranium), with higher concentrations occurring locally in thin chloritic zones and fractures. Consequently, groundwater seeping through fractures into open boreholes is highly anomalous in its radon content, with activity as high as 1 μ Ci/l. When total count gamma-ray logs are run in boreholes where groundwater inflow is appreciable, the result is quite unusual: the radon daughter activity in the water adds considerably to the gamma contribution from the rock, and in fact often dominates the log. The total gamma activity increases where radon-charged groundwater enters a borehole and decays as the water flows along the hole in response to the hydraulic gradient. (17 refs.)

78569 A branch grain theory of temperature gradient metamorphism in snow. R.A.Sommerfeld (USDA Forest Service, Rocky Mountain Forest & Range Experiment Station, Fort Collins, CO, USA).

J. Geophys. Res. (USA), vol.88, no.C2, p.1484-94 (20 Feb. 1983). Temperature gradient metamorphism in snow results in the development of branch grains at the expense of other types of grains. At constant density, the development of branch grains decreases the strength, thermal conductivity, and crystal number density while increasing the mean crystal size. A theory is developed that uses the following major assumptions: (1) at growth sites the thermal gradient is a function of crystal separation and (2) vapor flux is a function of local thermal gradient. A computer model based on the theory is compared with stereological measurements of snow from a carefully controlled experiment. (26 refs.)

78570 Erosional process of fine cohesive sediments. T.Kusuda, T.Umita, Y.Awaya (Dept. of Civil Engng. Hydraulics, Kyushu Univ., Fukuoka, Japan). *Mem. Fac. Eng. Kyushu Univ. (Japan)*, vol.42, no.4, p.317-33 (Dec. 1982). [received: May 1983]

A series of erosion tests on fine cohesive sediment by use of an annular flume was performed to investigate the characteristics of the erosional process. The critical shear stress defined as a stress above which deposit is slightly eroded is shown to depend on the solid fraction of deposit. The initial rate of erosion is given as an exponential function of shear stress. The erosional process at a constant shear stress is divided into two phases. One is a relatively rapid erosion phase. Another is a slow erosion phase in which rheopexy and the armoring effect appear in the uneroded deposit, and they make deposit resistant on erosion. In the erosional process at a stepwise changed shear stress, the most important factor to estimate the rate of erosion for fine cohesive sediments is found to be shear stress history due to rheopexy. (12 refs.)

78571 Comparison of CO₂ measurements by two laboratories on air from bubbles in polar ice. J.M.Barnola, D.Raynaud (Lab. de Glaciologie et de Geophys. de l'Environnement, Grenoble, France), A.Neffel, H.Oeschger. *Nature (GB)*, vol.303, no.5916, p.410-13 (2 June 1983).

The CO₂ content of air enclosed in bubbles in polar ice has previously been reported by our two laboratories (in Grenoble and Bern) to be representative of the atmospheric CO₂ concentration at the time the ice was formed. Both laboratories are currently measuring various ice cores in order to determine the pre AD 1850 CO₂ level in the atmosphere, which relates to the partitioning of anthropogenic CO₂ among the atmospheric, biospheric and oceanic reservoirs. The two laboratories use different ice cores and different analytical procedures and need to know to what extent the measurements are quantitatively comparable. The authors present the results of a comparison between the two laboratories based on measurements from the same ice core sections, which indicate that the measurements can be compared with great confidence. (9 refs.)

78572 Computer simulation in flood forecasting. E.Thro. *Simulation (USA)*, vol.40, no.3, p.105-6 (March 1983). Describes FLUVIAL, a model based on several principles of river dynamics. In its virgin state a river balances the power it expends along its length to find a state of equilibrium. Human activities, such as mining or bridge building, distort the natural balance and cause the river to seek a new equilibrium. According to the theory of minimum power, a river adjusts its width to minimize power expenditure. The current molds the channel so that each segment does equal work. When a river expends power equally along its channel, it uses the minimum power over its reach (length). This principle is used to simulate river changes. Using FORTRAN, FLUVIAL calculates three kinds of river changes: bed elevation, channel width, and lateral migra-

tion (the sideways movement of the bed within the floodplain). Several measurements are used in FLUVIAL simulation: water routing, sediment routing and stream width and profile. (no refs.)

78573 Detection of abrupt changes occurring in a rainfall sequence represented by a periodic function. T.Ueda, K.Jinno, A.Kawamura, S.Takayoshi.

Technol. Rep. Kyushu Univ. (Japan), vol.55, no.6, p.585-91 (Dec. 1982). In Japanese. [received: May 1983]

By assuming that a rainfall sequence is represented by a periodic function, the adaptive Kalman filtering theory coupled with a generalized likelihood ratio test satisfactorily detects the presence of abrupt changes of a system occurring in the sequence and estimates their magnitudes and time of occurrence. Whereas the ordinary Kalman filter cannot be employed even in the detection of the abrupt changes, this adaptive Kalman filtering theory also accurately achieves the compensation of the forecast values. Simplification of this theory shortens CPU time and decreases the use of a large number of memory storages. (10 refs.)

78574 Snow avalanche motion and related phenomena. E.J.Hopfinger (Inst. de Mecanique, Univ. de Grenoble, Grenoble, France).

In book: *Annual review of fluid mechanics. Vol.15*, M.Van Dyke, J.V.Wehausen, J.L.Lumley [Ed.], p.47-76. Palo Alto, CA, USA: Annual Reviews (1983), 534 pp. [0 8243 0715 1]

Different types of avalanches are classified morphologically. Snow release mechanisms are discussed. The flow characteristics of avalanches are considered. Impact forces and airborne powder avalanches are also considered. (82 refs.)

78575 Investigation of the medium temperature at 11.7 GHz [microwave attenuation estimation]. W.Riedler, R.Lang (Inst. fur Nachrichtentech. und Wellenausbreitung, Tech. Univ. Graz, Graz, Austria).

Arch. Elektron. & Uebertragungstechnik (Germany), vol.37, no.5-6, p.199-202 (May-June 1983).

The temperature of the propagating medium is an important parameter for investigations of the attenuation characteristics of satellite paths. Using experimental results from the satellite OTS as well as from radiometers it is shown in the paper, that in many cases the widely used value of 270K leads to a severe underestimation of the expected attenuation and that a value of ca. 235K is more adequate. (5 refs.)

78576 On the calculation of total solar radiation. II. Huang Runben, Deng Hanzeng, Liu Senyuan.

Acta Sci. Nat. Univ. Sunyatseni (Zhongshandaxue Xuebao) (China), no.4, p.117-21 (1982). In Chinese.

Some parameters used to calculate the total solar radiation in the Averkiev formula are given a further treatment. Besides, some numeric data of calculating the total solar radiation appropriate to South China are given. (9 refs.)

78577 Rain day frequency and mean daily rainfall intensity as determinants of total rainfall over the eastern Orange Free State. M.S.J.Harrison (Climatology Res. Group, Univ. of the Witwatersrand, Johannesburg, S Africa).

J. Climatol. (GB), vol.3, no.1, p.35-45 (Jan.-March 1983).

Summer rainfall totals over the eastern Orange Free State are described in terms of number of days of rain and of mean rainfall per rain day. Variations in rainfall may be considered to result from frequency changes in an objectively-chosen subset of significant rain days. It is demonstrated that increases in mean rainfall per rain day result from an increased number of, and increased intensity of, rain on, the heaviest rain days. Some implications of these findings for studies of atmospheric circulation changes and for weather modification are discussed. (39 refs.)

78578 Numerical experiments on airflow patterns around a cone-shaped island. S.Ishijima (Junior Coll. Div., General Education Univ. of the Ryukyus, Okinawa, Japan).

Bull. Coll. Sci. Univ. Ryukyus (Japan), no.35, p.81-106 (March 1983).

Airflow patterns revealed as perturbations in the large scale prevailing airflow due to the topographical effect are studied with the aid of the mixed layer integrated numerical model. The author discusses the Froude Number, the Coriolis force, the frictional force, the heat and moisture vertically transported from the Earth surface, and the precipitation. (12 refs.)

78579 Aerosols within the World Climate Research Programme. D.Spankuch (Main Meteorological Obs., Potsdam, Germany).

Adv. Space Res. (GB), vol.2, no.5, p.1-2 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

Based on the findings of the meeting of Joint Scientific Committee experts on 'Aerosol and Climate' (Geneva, 27-31 October 1980) the general research strategy consisting of three phases presented. Phase I: sensitivity tests with available models. Phase II: improvement of climate models and data bases. Phase III: development of advanced climate models with internal aerosol generation and regulation processes. COSPAR's role within this research strategy is outlined. (3 refs.)

78580 The effect of aerosols on climate and aerosol climatology on the basis of observations from space. K.Ya.Kondratyev, A.A.Grigoryev, O.M.Pokrovsky (Main Geophysics Obs., State Committee for Hydrometeorology & Control of the Natural Environment, Moscow, USSR).

Adv. Space Res. (GB), vol.2, no.5, p.3-10 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

Principal aspects of the effect of aerosols on climate are discussed and the possibilities of obtaining a climatic data set of global aerosols are analyzed. Based on the analysis of space images, new data are obtained on gigantic dust outbreaks in various regions of the Earth. It is shown that dust outbreaks can propagate over hundreds and sometimes thousands of kilometers. (29 refs.)

78581 The role of aerosols in the climate system: results of numerical experiments in climate models. R.A.Reck (Phys. Dept., General Motors Res. Labs., Warren, MI, USA).

Adv. Space Res. (GB), vol.2, no.5, p.11-18 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

Three principal questions are recurrent with the consideration of an aerosol related climatic effect: (1) do aerosols heat or cool the atmosphere, (2) are aerosol climatic effects significant and (3) can numerical models be validated by predicting a climatic change associated with a measured aerosol-event? Each of these questions is addressed from a historical perspective. In addition, aerosol-related modeling is discussed as well as recommendations for future research. (57 refs.)

78582 Aerosol observations from Nimbus-7 CZCS along the South African west coast. N.M.Walters, O.G.Malan, D.C.Neethling (Nat. Phys. Res. Lab., CSIR, Pretoria, S Africa).

Adv. Space Res. (GB), vol.2, no.5, p.105-7 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

In the course of the South African participation in the Nimbus-7 coastal zone colour scanner project, a fair amount of cloud-free data were collected along the South African west coast, mainly to study upwelling phenomena. Examples of aerosol radiance maps produced during analysis of these data, including some anomalous results, are discussed. (9 refs.)

78583 Satellite measurements of tropospheric aerosols. M.Griggs (Electronic Vision & Systems Div., Sci. Applications, Inc., San Diego, CA, USA).

Adv. Space Res. (GB), vol.2, no.5, p.109-18 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

A global-scale ground-truth experiment was conducted in 1980 with the AVHRR on NOAA-6 to determine the relationship between the upwelling visible radiance and the aerosol optical thickness at ten ocean sites around the globe. The data for four sites have been analyzed, and the aerosol contents measured by the AVHRR and by sunphotometers are compared. A preliminary analysis of AVHRR Channel 1 (0.65 μm) and Channel 2 (0.85 μm) radiances suggest that useful information on the aerosol size distribution may also be obtained from satellite observations. (9 refs.)

78584 Monitoring of Saharan dust over the Atlantic using Meteosat-VIS-data. M.Kastner, P.Kopke, H.Quenzel (Meteorologisches Inst., Univ. Munchen, Munchen, Germany).

Adv. Space Res. (GB), vol.2, no.5, p.119-21 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

The optical depth of Saharan dustclouds (a component of the radiation budget), which can be clearly seen in satellite images taken over the Atlantic, can be determined from the Meteosat VIS-data. 'Favourable angles' between Sun, observed point and satellite are chosen so that the optical depth is determined with an accuracy of only about 20%. Several clouds, their change over time, and some of their other interesting features are presented. The results are discussed. (6 refs.)

78585 Can turbidity measurements be used for the estimation of aerosol parameters? D.Spankuch (Meteorological Service of Germany, Main Meteorological Obs., Potsdam, Germany), W.von Hoyningen-Huene.

Adv. Space Res. (GB), vol.2, no.5, p.131-4 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

In a previous paper (Zeitschrift fur Meteorologie, vol.29, p.146, 1979) the authors showed that the aerosol size distribution can be estimated with reasonable accuracy from spectral extinction measurements in a limited spectral region ($\lambda \leq 1 \mu\text{m}$) only. Using the same method they discuss whether the anticipated WMO turbidity network with four spectral channels has the potential of estimating the aerosol size distribution. (17 refs.)

78586 Rocket studies of atmospheric scattering and the aerosol size distribution in the troposphere and lower stratosphere over Thumba. B.H.Subbaraya, A.Jayaraman (Phys. Res. Lab., Ahmedabad, India).

Adv. Space Res. (GB), vol.2, no.5, p.135-8 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

Measurements have been made of the atmospheric scattering in the ultraviolet ($\lambda < 0.31 \mu\text{m}$) during the 16 February 1980 solar eclipse rocket campaign. The amplitude of the scattered fluxes as well as the angular distribution could be measured from ground up to an altitude of about 24 km. The Rayleigh scattering component was estimated using standard atmospheric models and the observations have been used to study the scattering due to aerosols at tropospheric and lower stratospheric altitudes. (7 refs.)

78587 On the quasi-biennial oscillation in equatorial stratospheric temperatures and total ozone. C.S.Zerefos (Phys. Dept., Univ. of Thessaloniki, Thessaloniki, Greece).

Adv. Space Res. (GB), vol.2, no.5, p.177-81 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

The results of a cross-spectral analysis between monthly mean temperatures at 100 mb, 50 mb and 30 mb over the equator and the corresponding monthly mean UV total ozone at different latitude zones are presented for the period 1970-1977. Significant squared coherences between total ozone and 50 mb equatorial temperatures at 26 months are only found between 5 degrees on each side of the equator, between 45 deg N and 55 deg N and at 45 deg S. At latitudes where the QBO in stratospheric temperature diminishes so does the QBO in total ozone. Over subtropical latitudes there is a tendency towards a more biennial oscillation in total ozone and at 65 deg N and 65 deg S total ozone oscillates at periods greater than the equatorial QBO. (14 refs.)

78588 Global pictures of the ozone field, from high altitudes, from DE-I. G.M.Keating (NASA Langley Res. Center, Hampton, VA, USA), L.Frank, J.Craven, M.Shapiro, D.Young, P.Bhartia.

Adv. Space Res. (GB), vol.2, no.5, p.183-8 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

Using the imaging instrumentation aboard the Dynamics Explorer spacecraft (DE-I), total column ozone densities are obtained in the sunlit hemisphere by measuring the intensities of backscattered solar ultraviolet radiation. The high apogee altitude (23000 km) of the eccentric polar orbit allows high resolution global-scale images of the terrestrial ozone field to be obtained within 12 minutes. Previous ozone-monitoring spacecraft have required much longer time periods for comparable spatial coverage because of their lower altitudes ($< 1200 \text{ km}$). The much higher altitude of DE-I also provides hours of continuous imaging of features compared to minutes or seconds with previous spacecraft. Near perigee, high resolution images can be gained with pixel size as small as 3 km to view mesoscale atmospheric variations. The effects of planetary-scale, synoptic-scale, and mesoscale dynamical processes, which control the distribution of ozone near the tropopause, can be studied. (16 refs.)

78589 Measurements of atmospheric ozone from aircraft and from balloons. W.A.Matthews (Max-Planck-Inst. fur Aeronomie, Katlenburg-Lindau, Germany).

Adv. Space Res. (GB), vol.2, no.5, p.189-95 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

The first ozone data from the Northern Hemisphere meridional flight 'SIMOC' are presented. The flight was made in May of 1981 from Germany up to 82°N and then down to the Equator and back with the Falcon 20E German research aircraft. These data include those obtained using a differential solar absorption spectrometer developed and built at the Max-Planck-Institut fur Aeronomie in Lindau. Ozone profiles obtained from an intensive series of balloon flights launched in northern Sweden over a two-week period are also presented and discussed in terms of the variability in ozone concentration that they demonstrate in the middle atmosphere. (3 refs.)

78590 A mesospheric ozone profile at sunset. H.Yamamoto, H.Sekiguchi, T.Makino (Dept. of Phys., Rikkyo Univ., Tokyo, Japan), T.Watanabe, K.S.Zalpur, T.Ogawa.

Adv. Space Res. (GB), vol.2, no.5, p.197-9 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

An altitude profile of the ozone concentration from 55 to 95 km was measured at sunset in January by simultaneous measurements of the 1.27 μm radiation and the solar UV radiation using rocket-borne radiometers at Uchinoura, Japan (31°N). The ozone profiles deduced by two different methods agree with each other at approximately 70 km. The profile was consistent with previous results obtained at the same station in September, and with the sunset profile obtained at Wallops Island (38°N) during the WMO/FAA/NASA international ozone rocketsonde intercomparison. The data show no seasonal variation of ozone in the 55-95 km region at Uchinoura. (9 refs.)

78591 Periodic and aperiodic ozone variations in the middle and upper stratosphere. J.London (Dept. of Astro-Geophysics, Univ. of Colorado, Boulder, CO, USA).

Adv. Space Res. (GB), vol.2, no.5, p.201-4 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

Umkehr, ozonesonde and satellite observations are used to determine the height/latitude distribution of the amplitude and phase of the periodic components of the variation of the ozone mixing ratio in the middle and upper stratosphere. The amplitude of the first (annual) harmonic is small in the subtropics and increases to a maximum at polar latitudes. It also increases with height in the mid and upper stratosphere to an apparent maximum just below the stratopause. The second (semi-annual) harmonic has an amplitude that is largest in tropical regions and in subpolar regions at a level of about 40 km. The phase of the first harmonic shows a marked transition from a winter/spring maximum below 30 km to a summer maximum at 30 km, changing rapidly to a maximum in winter in both hemispheres. (8 refs.)

78592 Solar eclipse induced variations in mesospheric ozone concentrations. S.Lal, B.H.Subbaraya (Phys. Res. Lab., Ahmedabad, India).

Adv. Space Res. (GB), vol.2, no.5, p.205-8 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

A model study of the solar eclipse induced variations in mesospheric ozone concentrations was undertaken. This study includes, in addition to the Chapman reactions, the chemistry involving hydrogen species (H , OH and HO_2) which are found to be important in the destruction of odd oxygen in this altitude region. Coupled time dependent continuity equations are solved for the eclipse duration. The results from the present study are compared with earlier theoretical model and the experimental observations during the 16 February 1980 solar eclipse as well as the results obtained during earlier solar eclipses. (18 refs.)

78593 Solar UV and ozone balloon measurements. D.J.McEwen, P.Chakrabarty (Inst. of Space & Atmospheric Studies, Univ. of Saskatchewan, Saskatoon, Saskatchewan, Canada).

Adv. Space Res. (GB), vol.2, no.5, p.209-12 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

Absolute solar UV spectra were obtained with a $1/4$ m spectrometer on a balloon flight from Palestine, Texas, on September 23, 1981. This balloon reached a float altitude of 39 km at solar noon. The ozone density profiles derived from these spectra are discussed. The measurements are compared with data obtained from the same calibrated instrument flown in 1976 at solar minimum. (6 refs.)

78594 Modelling of the ion composition of the middle atmosphere. L.Thomas (Dept. of Phys., Univ. Coll. of Wales, Aberystwyth, Wales).

Ann. Geophys. (France), vol.1, no.1, p.61-73 (Jan.-Feb. 1983).

Discusses the nature of the primary ions produced during the ionization processes and information on ion composition. Model studies of the composition at D and E regions, which have attracted considerable attention over the past decade, are reviewed in some detail. For stratospheric heights, the treatment is restricted to a consideration of reaction schemes describing the chemistry which produce the positive and negative ions which have recently been identified. (101 refs.)

78595 Comparison of the bistatic cross-section and reflectivities of spherical and spheroidal raindrops at microwave frequencies. D.G.Charlton, A.R.Holt, B.G.Evans (Univ. of Essex, Colchester, England).

IEE Proc. F (GB), vol.130, no.4, p.317-24 (June 1983).

Investigates one aspect of the validity of models currently used to calculate rain-scatter interference in radio and satellite communication systems. Exact bistatic scattering cross-sections from spheroidal shaped raindrops are compared with those obtained from spheroids in the Rayleigh approximation and from spheres using the Mie theory at 11.7, 20 and 30 GHz. Comparisons are also made between bistatic radar reflectivities for rain populations at these frequencies. It is found that both the Rayleigh and Mie (sphere) approximations to the spheroidal raindrop yield errors in the bistatic scattering reflectivities. These errors can be significant in the case of the Rayleigh theory, but the Mie theory, in general, yields much closer results to the exact. (23 refs.)

78596 The optical and radiation field signatures produced by lightning return strokes. Changming Guo, E.P.Krider (Inst. of Atmospheric Phys., Univ. of Arizona, Tucson, AZ, USA).

J. Geophys. Res. (USA), vol.87, no.C11, p.9813-22 (20 Oct. 1982). [received: May 1983]

The optical signals radiated by Florida lightning in the 0.4- to 1.1- μ m wavelength interval have been recorded in correlation with wide-band electric field signatures. The initial light signal from a return stroke tends to be linear for about 15 μ s and then rises more slowly to a peak that is delayed about 60 μ s from the electric field peak. The transition between the fast linear portion and the slower rise may be due to the return stroke entering the cloud base. A small percentage of the records indicate that two different branches of the same stepped leader can initiate separate return strokes. The light pulses from cloud discharges tend to be smaller and more slowly varying than those from return strokes. The total optical power radiated by first strokes in the 5- to 35-km range has a mean and standard deviation of $2.3 \pm 1.8 \times 10^9$ W at peak. (56 refs.)

78597 Parameterization of IR cooling in a middle atmosphere dynamics model. I. Effects on the zonally averaged circulation. J.P.Apruzese, M.R.Schoeberl, D.F.Strobel (Plasma Phys. Div., Naval Res. Lab., Washington, DC, USA).

J. Geophys. Res. (USA), vol.87, no.C11, p.8951-66 (20 Oct. 1982). [received: May 1983]

A computationally efficient two-stream parameterization of IR cooling is developed for a middle atmosphere dynamics model. The parameterization combines the monochromatic feature of an emissivity formulation with the computational simplicity of a single spatial integral to evaluate the monochromatic transfer equation. The calculations show strong radiative control of the mesopause region (radiative relaxation rate $> [5 \text{ days}]^{-1}$) and the need for substantial deceleration of the mean zonal winds ($\sim 40 \text{ m s}^{-1} \text{ day}^{-1}$). Calculated temperatures show good agreement in the summer hemisphere where planetary wave activity is negligible, but in the polar night of the winter hemisphere they are ~ 30 K too cold which suggests planetary wave heating must make up the deficit. With observed ozone densities the globally averaged radiative equilibrium temperatures in the 65-75 km region are too cold and an additional heat source $\sim 1 \text{ K day}^{-1}$ is required. (42 refs.)

78598 Nitric acid column densities over Antarctica. W.J.Williams, J.J.Kosters, D.G.Murcray (Dept. of Phys., Univ. of Denver, Denver, CO, USA).

J. Geophys. Res. (USA), vol.87, no.C11, p.8976-80 (20 Oct. 1982). [received: May 1983]

Nitric acid column densities derived from atmospheric infrared spectral emission data measured from the NSF USARP C130 research aircraft in the Spring of 1978 are presented, summarized by latitude. An increase of the column density with latitude is noted, along with a longitudinal asymmetry in the latitudinal dependence. Column densities range in values from $1.2 \pm 0.2 \times 10^{20}$ molecules m^{-2} at 53° S latitude to $3.4 \pm 0.7 \times 10^{20}$ molecules m^{-2} at 89° S latitude. Also, the liquid helium cooled spectral radiometer used to obtain the data and the associated calibration procedures are described. (13 refs.)

78599 The quasi-biennial oscillation in atmospheric ozone. S.J.Oltmans (NOAA, Boulder, CO, USA), J.London.

J. Geophys. Res. (USA), vol.87, no.C11, p.8981-9 (20 Oct. 1982). [received: May 1983]

Analysis of various characteristics of the statistical spectra of total ozone covering a 15 year period (1964-78), and of ozone in the stratosphere over a period of about 7 years, indicates that the strong QBO in the zonal winds of

the tropical stratosphere is associated with a detectable, although often weak, signal in total ozone and the ozone concentration in the lower and middle stratosphere. The region of strongest relationship between tropical stratospheric zonal winds and total ozone (e.g. maximum ozone associated with strong west winds) is in the tropics, mid-latitudes of the southern hemisphere, and, apparently, at high latitudes of the northern hemisphere. (34 refs.)

78600 The Saudi Arabian heat low: aerosol distributions and thermodynamic structure. S.A.Ackerman, S.K.Cox (Dept. of Atmospheric Sci., Colorado State Univ., Fort Collins, CO, USA).

J. Geophys. Res. (USA), vol.87, no.C11, p.8991-9002 (20 Oct. 1982). [received: May 1983]

Radiation and microphysical data are employed to deduce the bulk radiative and microphysical characteristics of the aerosol layer over the Saudi Arabian Peninsula and the adjacent Arabian Sea. Observed particle size distributions, total mass loadings, and vertical distributions of the dust are presented for five analysis periods. There is a large daily variability of the dust mass loading over the desert. The broadband radiative characteristics of the dust are inferred by comparing calculations for a dust free atmosphere with in situ broadband radiative measurements. The dust had no detectable effect on the longwave radiation fluxes, while it approximately doubled the clear sky shortwave absorption. (19 refs.)

78601 Threshold friction velocities and rupture moduli for crusted desert soils for the input of soil particles into the air. D.A.Gillette (Air Resources Lab., NOAA, Boulder, CO, USA).

J. Geophys. Res. (USA), vol.87, no.C11, p.9003-15 (20 Oct. 1982). [received: May 1983]

Desert soils having clay crusts, mostly from the Mojave Desert, were tested for threshold friction velocity (the friction velocity at which soil erosion begins) with the open-bottomed wind tunnel. The soils were also tested for content of clay, water-soluble material, calcium carbonate, organic material, mineralogy of clay and of salts, soil moisture, modulus of rupture, and crust thickness. If no loose material existed on the soil surface, crusts having modulus of rupture greater than 0.7 bar and crust thickness of 0.7 cm to 0.3 cm were effective in protecting against wind erosion. Disturbed clay crusts having modulus of rupture before disturbance greater than 2 bar with thickness less than 1.9 cm did not experience significant wind erosion. Modulus of rupture was related to composition of soil but was shown to depend mostly on clay content. (20 refs.)

78602 Feedback mechanisms in the climate system affecting future levels of carbon dioxide. W.W.Kellogg (Nat. Center for Atmospheric Res., Boulder, CO, USA).

J. Geophys. Res. (USA), vol.88, no.C2, p.1263-9 (20 Feb. 1983). (Symposium on the Rise in Atmospheric Carbon Dioxide, Bern, Switzerland, 14-18 Sept. 1981).

The rate of increase of concentration of atmospheric carbon dioxide depends on the consumption of fossil fuels (the major source of 'new' carbon dioxide) and the natural sinks for this trace constituent, primarily the oceans and the biosphere. The rate of operation of these sinks depends on several factors determined by the state of the climate system, and they will therefore presumably change as the greenhouse effect of increasing carbon dioxide warms the earth. Five specific feedback loops are discussed, two of which are positive (amplifying the rate of increase), two are weakly negative and one is undetermined but probably positive. It is concluded that it would be well to be prepared for the possibility that carbon dioxide may increase faster than predicted by models on the current or past state of the climate system. (26 refs.)

78603 Three-dimensional tracer model study of atmospheric CO₂ response to seasonal exchanges with the terrestrial biosphere. I.Fung, K.Prentice, E.Matthews, J.Lerner, G.Russell (Inst. for Space Studies, NASA/Goddard Space Flight Center, New York, NY, USA).

J. Geophys. Res. (USA), vol.88, no.C2, p.1281-94 (20 Feb. 1983). (Symposium on the Rise in Atmospheric Carbon Dioxide, Bern, Switzerland, 14-18 Sept. 1981).

A three-dimensional tracer transport model is used to investigate the annual cycle of atmospheric CO₂ concentration produced by seasonal exchanges with the terrestrial biosphere. The tracer model uses winds generated by a global general circulation model to advect and convect CO₂; no explicit diffusion coefficients are employed. A biospheric exchange function constructed from a map of net primary productivity, and Azevedo's (1982) seasonality of CO₂ uptake and release closely simulates the annual cycles at coastal stations. The results show that zonal homogeneity in surface CO₂ concentrations can never be achieved at mid-latitudes where the time scale for zonal mixing is longer than the time scale for biospheric exchange. Analysis of the zonal mean balance in the lower troposphere reveals that atmospheric transport processes may alter the CO₂ response to local biospheric exchanges by 50% or more. (23 refs.)

78604 Exponential growth and atmospheric carbon dioxide. J.A.Laumann (Gas Res. Inst., Chicago, IL, USA), R.M.Rotty.

J. Geophys. Res. (USA), vol.88, no.C2, p.1295-9 (20 Feb. 1983). (Symposium on the Rise in Atmospheric Carbon Dioxide, Bern, Switzerland, 14-18 Sept. 1981).

The adequacy of assumptions required to project atmospheric CO₂ concentrations in time frames of practical importance is reviewed. Relevant issues concern the form assumed for future fossil fuel release, carbon cycle approximations, and the implications of revisions in fossil fuel patterns required to maintain atmospheric CO₂ levels below a chosen threshold. In general, it was found that with a judiciously selected exponential fossil fuel release rate, and with a constant airborne fraction, it is possible to estimate atmospheric CO₂ growth over the next 50 years based on essentially surprise free scenarios. Resource depletion effects must be included for projections beyond about 50 years, and on this time frame the constant airborne fraction approximation has to be questioned. (13 refs.)

78605 CO₂ and radon 222 as tracers for atmospheric transport. H.Dorr, B.Kromer, I.Levin, K.M.Unnich, H.-J.Volpp (Inst. für Umweltphys., Univ. of Heidelberg, Heidelberg, Germany).

J. Geophys. Res. (USA), vol.88, no.C2, p.1309-13 (20 Feb. 1983). (Symposium on the Rise in Atmospheric Carbon Dioxide, Bern, Switzerland, 14-18 Sept. 1981).

Time variations of the CO₂ concentration and the radon 222 daughter activity in the atmosphere are observed 16 m above the ground in the outskirts of Heidelberg (Germany), situated in the rather densely populated and intensively cultivated upper Rhine valley. These parallel recorded data series are used to estimate the CO₂ respiration rate from the soil and from plant leaves. Atmospheric concentration variations of both gases appear to be merely due to variations in atmospheric mixing. From direct measurements of concentration profiles in the soil air the authors deduce the ²²²Rn exhalation rate, which is nearly constant with time and about 4000 dpm $\text{m}^{-2} \text{ h}^{-1}$. This flux is consistent with the one derived from observed pileup of the ²²²Rn activity of an air mass during passage over the continent. (16 refs.)

- 78606 Preliminary study of CO₂ variations at Amsterdam Island (Territoire des Terres Australes et Antarctiques Françaises).** A.Gaudry, J.M.Ascencio, G.Lambert (Centre des Faibles Radioactivités, CNRS, Gif sur Yvette, France). *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1323-9 (20 Feb. 1983). (Symposium on the Rise in Atmospheric Carbon Dioxide, Bern, Switzerland, 14-18 Sept. 1981).
- The preliminary measurements of atmospheric CO₂ concentrations performed at Amsterdam Island between April and the end of 1980 showed two kinds of short-term variations. The first one, attributed to local effects of the photosynthesis of the island vegetation, does not seem considerably to affect the monthly mean CO₂ concentrations. The second one has been attributed to long range transport phenomena. That corresponds to large scale meteorological perturbations and generally is correlated with variations of the atmospheric radon concentrations. Therefore, the existence of regional CO₂ sources and sinks in the southern hemisphere can be felt at a very large distance. (13 refs.)
- 78607 Interpretation of atmospheric CO₂ measurements at Mt. Cimone (Italy) related to wind data.** L.Ciattaglia (Vigna di Valle Obs., Rome, Italy). *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1331-8 (20 Feb. 1983). (Symposium on the Rise in Atmospheric Carbon Dioxide, Bern, Switzerland, 14-18 Sept. 1981).
- Technical details on the apparatus and the CO₂ program at Mt. Cimone are reported, together with information on the sampling site and on the wind regime. Hourly values of atmospheric CO₂ are examined, and a preliminary interpretation is given, taking into account simultaneous observations of wind direction and wind speed at Mt. Cimone. In particular, a seasonal CO₂ trend is clearly identified along with a CO₂ dependence on synoptic situations, especially wind speed and direction. (6 refs.)
- 78608 Concentration of atmospheric carbon dioxide over Japan.** M.Tanaka, T.Nakazawa, S.Aoki (Upper Atmosphere Res. Lab., Tohoku Univ., Sendai, Japan). *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1339-44 (20 Feb. 1983). (Symposium on the Rise in Atmospheric Carbon Dioxide, Bern, Switzerland, 14-18 Sept. 1981).
- Aircraft measurements of atmospheric CO₂ concentration over Japan have been initiated in January 1979 at the Upper Atmosphere Research Laboratory of the Tohoku University. An average annual increase of CO₂ concentration during a period from the beginning to April 1981 is estimated to be 1.5 ppmv/year. Yearly average values for the concentration decrease rapidly with increasing height above ground, in the lowest layer of the troposphere, and decrease slightly in the layer above it, showing that the ground acts as a CO₂ source. The amplitude of the seasonal variation decreases markedly with elevation. The maximum occurs early in May and the minimum early in August at low levels. (17 refs.)
- 78609 Sampling strategy to obtain data used in models of global annual CO₂ increase and global carbon cycle.** D.A.Gillette (Air Resources Labs., Boulder, CO, USA), K.J.Hanson. *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1345-8 (20 Feb. 1983). (Symposium on the Rise in Atmospheric Carbon Dioxide, Bern, Switzerland, 14-18 Sept. 1981).
- Simple models were constructed to assess with somewhat limited CO₂ data the effects of both frequency of sampling and spatial distribution of sampling locations on the variance of estimates of interest to the global carbon cycle. The CO₂ data for use in these models were obtained from seven air flask sampling locations, globally distributed in latitude but restricted to the longitude sector 80°W to 170°W, during the period 1977-1979. The results of analysis with these models show (1) that locations north of 30°N are quite important in possibly providing information on carbon cycle exchange processes and that (2) improved sampling techniques including greater sampling frequency would be desirable for sampling locations in the southern hemisphere. (7 refs.)
- 78610 Selection of CO₂ concentration data from whole-air sampling at three locations between 1968 and 1974.** D.A.Gillette (Air Resources Labs., NOAA, Boulder, CO, USA), A.T.Steele. *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1349-59 (20 Feb. 1983). (Symposium on the Rise in Atmospheric Carbon Dioxide, Bern, Switzerland, 14-18 Sept. 1981).
- Three methods for rejection of CO₂ data were used to obtain CO₂ concentration versus time for 1968-1973 for Station Charlie (a ship in the North Atlantic), Niwot Ridge near Nederland, Colorado, and Key Biscayne near Miami, Florida. From examination of the results it was concluded that short-term variation and error were not large for the Station Charlie data. There was a suggestion of occasional contamination at Key Biscayne and evidence of more frequent contamination at Niwot Ridge, after 1970. Values obtained for annual CO₂ increases were 1.3 and 1.2 ppm (1959 SIO index) for Station Charlie and Niwot Ridge. Annual amplitudes were 5, 11 and 9.7 ppm for Station Charlie, Niwot Ridge, and Key Biscayne, respectively. (10 refs.)
- 78611 Tropospheric NO_x and O₃ budgets in the equatorial Pacific.** S.C.Liu, M.McFarland, D.Kley (NOAA, Aeronomy Lab., Boulder, CO, USA), O.Zafriou, B.Huebert. *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1360-8 (20 Feb. 1983).
- By combining the results of model calculations and simultaneous measurements of O₃, NO, HNO₃, particulate NO₃⁻, and meteorological parameters in the mid-Pacific, the authors have investigated the budget and photochemistry of near surface atmospheric ozone and odd nitrogen. The observed decrease of O₃ toward the Intertropical Convergence Zone is consistent with the transport of O₃ from higher latitude and a photochemical sink for O₃ by the reaction between H₂O and O(¹D). The total deposition flux of odd nitrogen deduced from the data is about $1.3 \times 10^9 \text{ cm}^{-2} \text{ s}^{-1}$ deposition flux is due to HNO₃ and particulate NO₃⁻. Since the residence time of odd nitrogen in the lower troposphere is short, a widely distributed, diffuse source of odd nitrogen is required to balance the deposition flux. It seems that the NO formed by cloud lightning is the most likely source. (73 refs.)
- 78612 The sources of sulfate in precipitation. I. Parameterization scheme and physical sensitivities.** D.A.Hegg (Atmospheric Sci. Dept., Univ. of Washington, Seattle, WA, USA). *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1369-74 (20 Feb. 1983).
- The parameterization scheme for sulfate washout derived by Scott see J. Appl. Meteorol., vol.17, p.1375-89 (1978) is modified to allow estimation of the relative contributions of nucleation scavenging, in-solution production, and below-cloud scavenging to the sulfate content of precipitation. The parameterization scheme predicts changes in precipitation sulfate concentration by up to a factor of 6 for large variations in key cloud physics parameters. The results suggest in-solution sulfate production can be a substantial contributor to the sulfate content of precipitation. (24 refs.)

- 78613 The sources of sulfate in precipitation. II. Sensitivities to chemical variables.** R.J.Charlson, R.Vong, D.A.Hegg (Dept. of Civil Engng., Univ. of Washington, Seattle, WA, USA). *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1375-7 (20 Feb. 1983).
- For pt.1 see ibid., vol.88, no.C2, p.1369-74 (1983). A convective cloud model used to examine the relative contribution to sulfate in rain of nucleation scavenging (NS) below-cloud scavenging (BCS) and in cloud production of sulfates (SP) shows that considerable variation may be expected due to change in the amounts of input sulfur species. The case of high input of both SO₂ and SO₄²⁻ bearing aerosol (industrial case) shows SP to be dominant while low inputs yield results ranging from NS and SP being roughly equal to dominance by NS. For the conditions chosen, BCS is low. The sensitivities of the partitioning between these three pathways to changes in SO₂, SO₄²⁻ aerosol, and pH are briefly surveyed. (3 refs.)
- 78614 A numerical model of the zonally averaged dynamical and chemical structure of the middle atmosphere.** R.R.Garcia (Nat. Center for Atmospheric Res., Boulder, CO, USA), S.Solomon. *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1379-400 (20 Feb. 1983).
- A two-dimensional, time-dependent model has been constructed to study the zonally averaged structure of the middle atmosphere (16-116 km) allowing interaction among dynamics, radiation and photochemistry. The zonally averaged dynamics are governed by a stream function equation for the residual Eulerian meridional circulation wherein the effects of wave transience and dissipation have been neglected. The resulting circulation is thus driven by diabatic heating and cooling, with Rayleigh friction introduced to balance the momentum budget. The temperature structure is computed from the zonal mean thermodynamic equation, while the appropriate continuity equations are solved to determine the distribution of the various chemical species and families. In the chemical continuity equations, two types of eddy transport processes are present in addition to the transport by the residual Eulerian circulation. (101 refs.)
- 78615 On the relationship between the greenhouse effect, atmospheric photochemistry, and species distribution.** L.B.Callis (NASA Langley Res. Center, Hampton, VA, USA), M.Natarajan, R.E.Boughner. *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1401-26 (20 Feb. 1983).
- A radiative-convective-photochemical model that extends from 0 to 53 km is used to examine the effect on atmospheric constituents and thermal structure of changes in the atmospheric levels of CO₂, CFMs, CO, N₂O and combinations of these species. Calculations were carried out for two reference atmospheres, one with high (HINOX) and one with low (LONOX) levels of NO_x. The HINOX troposphere provides a net photochemical source of O₃ and is not greatly sensitive to downward transport of O₃ from the stratosphere. The LONOX troposphere is a photochemical sink for O₃ and, as a result, is sensitive to such variations in downward transport. Results of this study suggest that (1) infrared opacity changes due to CO₂ and CFM increases can cause significant changes in tropospheric O₃, OH, CH₃, CO, and other species through changes in tropospheric water vapor; (2) perturbation or sensitivity studies conducted with tropospheric photochemical models may be subject to significant errors due to the absence of modulating effects provided by the stratosphere. Some other findings of this model are described. (120 refs.)
- 78616 Chlorocarbon emission scenarios: potential impact on stratospheric ozone.** D.J.Wuebbles (Lawrence Livermore Nat. Lab., Univ. of California, Livermore, CA, USA). *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1433-43 (20 Feb. 1983).
- Prior analyses of chlorocarbons and their effects on stratospheric ozone have primarily concentrated on examining potential perturbations from two chlorofluorocarbons, CFCl₃ (CFC-11) and CF₂Cl₂ (CFC-12). The purpose of this study is to provide an updated theoretical analysis of the potential effect on ozone due to past and future chlorocarbon emissions. To assess the overall impact from chlorinated emissions on the ozone layer, all chlorocarbons presently thought to be of likely concern are examined. A broad spectrum of scenarios is evaluated in order to provide an envelope including conceivable changes in future chlorocarbon emissions. Results indicate that CFCl₃, CF₂Cl₂ (CFC-113), CH₂Cl₂, and CCl₄ could contribute significantly to predicted changes in total ozone based on their current emission rates. (46 refs.)
- 78617 Effect of coupled anthropogenic perturbations on stratospheric ozone.** D.J.Wuebbles, F.M.Luther, J.E.Penner (Lawrence Livermore Nat. Lab., Univ. of California, Livermore, CA, USA). *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1444-56 (20 Feb. 1983).
- In order to compare theoretical calculations of ozone levels with recent measurements of ozone and to project expected changes over the next few decades, one must consider the effect from perturbations other than from chlorofluorocarbons. In this paper, the coupling between several possible anthropogenic atmospheric perturbations is considered. The effects of past and possible future increases of chlorocarbons, CO₂, N₂O, and NO_x are examined. The focus of these calculations is on the potential changes in ozone due to chlorocarbon emissions, how other anthropogenic perturbations may have influenced the actual change in ozone over the last decade, and how these perturbations may influence future changes in ozone. There is very little change predicted in total ozone over the coming decades when other anthropogenic sources are included. Increasing CO₂ concentrations have the largest offsetting effect on the change in total ozone due to chlorocarbons. (67 refs.)
- 78618 Stratospheric sulfuric acid vapor: new and updated measurements.** A.A.Viggiano, F.Arnold (Max-Planck-Inst. für Kernphys., Heidelberg, Germany). *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1457-62 (20 Feb. 1983).
- The measurements of gas phase H₂SO₄ in the stratosphere have been continued. It has been realized that the measurements may include other sulfur-containing species such as HSO₃ and HSO₅. The technique has been improved through the use of a mass spectrometer with a larger mass range and better measurements of the parameters involved in the derivation of the H₂SO₄ concentration. The results from the first two flights of this new instrument are reported, and the older data have been revised in accordance with the new measurements of the parameters. In addition, the lower height range has been extended to 15 km. (35 refs.)
- 78619 Simultaneous measurements of vertical distributions of stratospheric NO₃ and O₃ at different periods of the night.** P.Rigaud (Station Sci. du Val Jouvey, Villepreux, France), J.P.Naudet, D.Huguenin. *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1463-7 (20 Feb. 1983).
- Simultaneous measurements of NO₃ and O₃ were performed at different periods of the night from stratospheric balloons launched from the CNES balloon station at Aire-sur-l'Adour in September 1980 and September 1981. The experimental NO₃ vertical profiles compare favorably with those predicted by the photochemical theory. Differences can be explained by the dependence of the recombination rate of NO₂ and O₃ upon altitude. The O₃ concentrations above 30 km measured by spectrophotometry around λ=660 nm present a remarkable stability. Measurements obtained by means of this technique could be used as a reference for the detection of long-term variations of O₃. (21 refs.)

78620 UV rocket spectroscopy measurement of the nighttime ozone distribution. J.L. Lean (Dept. of Phys., Univ. of Adelaide, Adelaide, Australia). *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1468-74 (20 Feb. 1983). Nocturnal ozone densities between 32 and 72 km have been derived from observations of the full Moon, made by three optical ozone detectors, each comprising three ultraviolet photometers. The three similar detectors were carried on a single spinning rocket, launched at Wallops Island on November 4, 1979. The mean of the three measured ozone profiles is consistent with other nighttime ozone profiles obtained from the LRIR satellite experiment and also from ground based millimeter wave observations. The relative standard error in the mean ozone profile is approximately 5%. At 70 km the ozone concentration of $1.5 \times 10^{19} \text{ cm}^{-3}$ is a factor of three greater than the US Standard Atmosphere, 1976 mid latitude daytime model. (29 refs.)

78621 A preliminary global oceanic cloud climatology from satellite albedo observations. N.A. Hughes (Dept. of Geography, Univ. of Liverpool, Liverpool, England), A. Henderson-Sellers. *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1475-83 (20 Feb. 1983). A pilot study has lead to the establishment of a preliminary predictive relationship for cloud amount as a function of satellite observed system albedo. The United States Air Force 3D-nephanalysis cloud archive is used as the source of cloud data and is compared with monthly mean system albedo values calculated by NOAA/NESS from the NOAA satellite scanning radiometer data at a resolution of 2.5° by 2.5° . The predictive relationship is applied to ocean areas to produce new global oceanic cloud climatologies. (20 refs.)

78622 Lightning propagation and flash density in squall lines as determined with radar. V. Mazur (Cooperative Inst. for Mesoscale Meteorological Studies, Univ. of Oklahoma, Norman, OK, USA), W.D. Rust. *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1495-502 (20 Feb. 1983). The propagation of lightning has been studied using radar techniques. The rise time of radar echoes is explained by ionized channel propagation through the radar beam. The calculated values agree well with those obtained experimentally. Measurements of the radial velocity of streamer propagation (along the antenna beam) show speeds of at least $2.5 \times 10^5 \text{ m/s}$. The time-range variations in lightning echoes are indicative of (1) new ionization as streamers develop into different parts of the cloud, (2) channel decay during which adequate ionization exists for radar detection, or (3) continuing current. Lightning flash density has been determined for two squall lines, one in the USSR and the other in the United States. The maximum lightning density tends to be near the leading edge of the precipitation cores in developing cells. As a cell in the squall line develops and the total lightning density increases, long discharges are produced, but shorter ones predominate. In contrast, as the cell dissipates, short flashes diminish or cease, and the long flashes dominate. (18 refs.)

78623 The seasonal variation of the atmospheric SO_2 to SO_4^{2-} conversion rate. J.F. Meagher, E.M. Bailey (Air Resources Program, Tennessee Valley Authority, Muscle Shoals, AL, USA), M. Luria. *J. Geophys. Res. (USA)*, vol.88, no.C2, p.1525-7 (20 Feb. 1983). Data collected during eight separate field studies conducted at four coal-fired power plants were combined to investigate the dependence of the nonaqueous phase SO_2 oxidation rate on various meteorological parameters. The data exhibited a strong seasonal trend with average morning SO_2 oxidation rates varying from a winter low of $1.5 \times 10^{-3} \text{ h}^{-1}$ to a summer high of $1.3 \times 10^{-2} \text{ h}^{-1}$. (11 refs.)

78624 Atmospheric gravity wave production for the total eclipse of 11 June 1983. G.L. Goodwin (School of Phys., South Australia Inst. of Technol., Ingle Farm, S. Australia). *J. Atmos. & Terr. Phys. (GB)*, vol.45, no.4, p.273-4 (April 1983). Internal atmospheric gravity bow waves generated by the eclipse of 11 June 1983 will focus over central Australia. (6 refs.)

78625 The wave properties in the process of nocturnal radiation inversion. Zhou Mingyu, Zhang Yi (Acad. Sinica, Beijing, China). *Kexue Tongbao (Foreign Lang. Ed.) (China)*, vol.28, no.2, p.216-20 (Feb. 1983). It is difficult to maintain the steady state of the stable atmospheric boundary layer, in which the meteorological elements often change. Therefore a study of the characteristics of the nocturnal atmospheric boundary layer, especially of the characteristics and development regularity of the radiation inversion process, has important significance for theoretical research of the atmospheric boundary layer and such practical problems as the transport and diffusion of atmospheric pollutants. (6 refs.)

78626 On the initialization in numerical weather prediction in the tropics. Zhou Jiabin, Wu Peizhen (Inst. of Atmospheric Phys., Acad. Sinica, Beijing, China). *Kexue Tongbao (Foreign Lang. Ed.) (China)*, vol.28, no.1, p.69-73 (Jan. 1983). [received: June 1983] Due to the undesirable sensitivity to initial values and small-scale disturbances of the primitive equation used for weather prediction in the tropics, nine initialization schemes are evaluated. These variously take into account the distinct characteristics for different latitudes, the linkage between levels in the vertical, and divergence in the initial field. They are assessed in a series of tests using a four-level primitive equation model. (8 refs.)

78627 Stratospheric NO_2 and upper limits of CH_3Cl and C_2H_6 from measurements at 3.4 μm . D.J.W. Kendall (Herzberg Inst. of Astrophys., Nat. Res. Council of Canada, Ottawa, Ontario, Canada), H.L. Buijs. *Nature (GB)*, vol.303, no.5914, p.221-2 (19 May 1983). Reports high resolution absorption spectra that have been obtained from a balloon-borne platform in the 3.4 μm spectral region, a region which contains bands due to several atmospheric constituent gas species including methane (CH_4), hydrochloric acid (HCl), nitrogen dioxide (NO_2), methyl chloride (CH_3Cl) and ethane (C_2H_6). From analysis of the atmospheric spectra obtained during sunset, mixing ratio versus altitude profiles have been obtained for HCl (which will be reported elsewhere) and NO_2 , and upper limits have been obtained for the lower stratospheric mixing ratios of CH_3Cl and C_2H_6 . (29 refs.)

78628 In situ aircraft measurements of enhanced levels of N_2O associated with thunderstorm lightning. J.S. Levine (Atmospheric Sci. Div., NASA Langley Res. Center, Hampton, VA, USA), E.F. Shaw, Jr. *Nature (GB)*, vol.303, no.5915, p.312-14 (26 May 1983). Reports the first series of measurements of enhanced levels of atmospheric N_2O associated with thunderstorm lightning. N_2O is an environmentally significant species since its reaction with excited oxygen (O^1D) in the stratosphere produces NO which through the catalytic NO_x cycle is responsible for about 65% of the total global destruction of ozone (O_3) in the stratosphere. In addition, due to its absorption at 7.8 μm in the atmospheric window, N_2O absorbs and then re-emits Earth-emitted IR radiation which leads to an enhancement of the surface temperature, and hence, has important implications for climate considerations. (21 refs.)

78629 Positive ion composition measurements and acetonitrile in the upper stratosphere. E.A. Jijds, D. Nevejan, J. Ingels (Belgian Inst. for Space Aeronomy, Brussels, Belgium). *Nature (GB)*, vol.303, no.5915, p.314-16 (26 May 1983). Reports the first positive ion composition data obtained using a balloon-borne instrument between 42 and 46 km altitude. These data extend the density profile of molecule X and give supplementary indications about its identity. The data were obtained with a mass spectrometer that was flown on 23 September 1982 on a stratospheric balloon from the CNES launching base of Aire-sur-l'Adour (44°N). (27 refs.)

78630 The role of radar in weather forecasting. K.A. Browning (Radar Res. Lab., Royal Radar Estab., Malvern, England). *Phys. Technol. (GB)*, vol.14, no.3, p.140-5 (May 1983). Radar is a versatile observational tool in meteorology. The author discusses the use of networks of weather radars for tracking rain areas and thunderstorms. Doppler radars can detect the hazardous winds sometimes associated with such storms. (3 refs.)

78631 The global distribution of thunderstorm activity observed by the ionosphere sounding satellite (ISS-b). M. Kotaki, I. Kuriki, C. Katoh, H. Sugiuchi. *Rev. Radio Res. Lab. (Japan)*, vol.28, no.146, p.369-86 (June 1982). In Japanese. Observation of the global distribution of atmospheres, especially lightning discharges, has been made by means of four channel HF receivers on board the Ionosphere Sounding Satellite-b. The operational frequencies of the receivers are set in the guard band of the standard frequency transmission at 2.5, 5, 10 and 25 MHz so as to avoid interference from terrestrial radio transmitters. The count of lightning discharges which were observed was accumulated in each geographic bin ($10^\circ \times 10^\circ$ in both longitude and latitude) and normalized by the observation time for the area. Based on the data obtained during the period from June, 1978 to May, 1980, the active regions of lightning were mapped out in the form of global distribution divided into every four hours in universal time, 22-02, 02-06, 06-10, 10-14, 14-18, and 18-22 hr of a day for the four seasons. The authors estimate the global lightning frequency to be 64 sec^{-1} for the northern spring, 55 sec^{-1} for the summer, 80 sec^{-1} for the fall, and 54 sec^{-1} for the winter. The peak lightning frequency occurs at $10^\circ\text{-}20^\circ\text{S}$ during the northern winter and at $10^\circ\text{-}20^\circ\text{N}$ during the summer. The diurnal variation of global lightning frequency has a peak at 12 hr UT. (15 refs.)

78632 Global distribution of atmospheric radio noise derived from the global distribution of lightning activity. M. Kotaki, C. Katoh. *Rev. Radio Res. Lab. (Japan)*, vol.28, no.146, p.411-33 (June 1982). In Japanese. Based on global maps of thunderstorm activity measured by the Ionosphere Sounding Satellite-b the atmospheric radio noise levels over the world were calculated. Global distribution maps of atmospheric radio noise were made for frequencies of 2.5, 5, 10 and 20 MHz, for every four hours in universal time during autumn. The calculated results agree better with world-wide measurements than those given by CCIR report no.322, and, moreover, some characteristics of the atmospheric radio noise can be well explained by the present method. (15 refs.)

78633 The seasonal variation of wind speed in the United Kingdom. S.G. Smith (Meteorological Office, Bracknell, England). *Weather (GB)*, vol.38, no.4, p.98-103 (April 1983). Within the meteorological office a statistical model is being developed for simulating sequences of hourly mean wind speeds for different locations in the United Kingdom (UK). To achieve this it is necessary to describe the seasonal variation of wind speed and fit it to a mathematical function. Spatial differences in the seasonal variation are studied by using a common 15-year period of data for 20 stations. The long-term (100 years) seasonal variation is considered by recourse to monthly speeds obtained from surface pressure gradients. (4 refs.)

78634 Large falls of rain in Wales—a simple statistical case study. I.T. Jolliffe (Math. Inst., Univ. of Kent, Canterbury, England). *Weather (GB)*, vol.38, no.4, p.103-5 (April 1983). Perry and Howells (1982) presented data from various stations in South Wales in an attempt to answer the question 'Are large falls of rain in Wales becoming more frequent?' The tables and figures in that paper suggested persuasively that the answer is 'Yes' to the more specific question 'Are large falls...more frequent in the years 1926-1980 than before 1925?' However, the analysis of the data was purely descriptive, and no attempt was made to use statistical techniques to assess whether the differences between the two time periods could have arisen by chance. The author's note remedies this omission by presenting some relatively simple statistical analyses of the data. In doing so it illustrates the use in practice of three well-known probability distributions. (1 ref.)

78635 North-African cyclonic systems and springtime temperatures in Israel. M. Druryan (Dept. of Geography, Bar Ilan Univ., Ramat Gan, Israel). *Weather (GB)*, vol.38, no.4, p.110-11 (April 1983). Considers the fate of low pressure regions found over north-west Africa during the months March, April and May, as depicted by the Synoptic Weather Maps (of the Northern Hemisphere). Daily Series (1953-1968) and operational weather charts of the Israel Meteorological Service (1966-1967, 1970-1977). It is of primary interest to establish whether or not a particular cyclonic system eventually triggered a sharav (heat wave), and how the consequences were related to synoptic developments. Sharav was taken as having occurred on a day when the maximum temperature at Bet Dagan (about 10 km south-east of Tel Aviv) as recorded in Israel's Monthly Weather Summary (1953-63) was more than 5 deg C greater than its long-term mean (interpolated to each day from the monthly normals of daily maximum temperature). (5 refs.)

78636 Observations of abnormal microwave propagation phenomena during melting layer conditions. M. Kharadly (Univ. of British Columbia, Vancouver, BC, Canada), N. Owen, J. Van der Star, D. Michelson, T. Engren. Third International Conference on Antennas and Propagation ICAP '83, Norwich, England, 12-15 April 1983 (London, England: IEE 1983), p.214-18 part 2. Many investigators, including Watson (1976), Oomari and Aoyagi (1971), Austin (1964), and Van der Star and Kharadly (1981), have reported that the presence of a melting layer in a propagation channel increased the channel attenuation above that which could be attributed to rain. This paper presents, in addition to observations depicting severe cases of this phenomenon, other anomalous fading phenomena that were associated with the presence of the melting layer. These observations were made on a microwave slant path in British Columbia approximately 200 km inland from the Pacific Ocean. (8 refs.)

92.60S Climatology

- 78637 Persistence of wet and dry spells at Uccle (Belgium). A.Berger, C.Goossens (Inst. of Astron. & Geophys., Catholic Univ. of Louvain-la-Neuve, Louvain, Belgium). *J. Climatol. (GB)*, vol.3, no.1, p.21-34 (Jan.-March 1983). The rainfall persistence at Uccle (Belgium) is examined statistically using 75 years of daily observations. Different kinds of distributions expressing this persistence have been fitted to the sequences of dry and wet days: the geometric series, the logarithmic series, the Eggenberger-Polya distribution, the simple Markov Chain and the Markov Chain of order higher than one. Wet and dry spells are best described by a Markov Chain model of order four. Nevertheless, for wet days, the Eggenberger-Polya distribution provides a good fit to the observed data. For Uccle, the rainfall persistence seems to remain constant after four consecutive days of precipitation. (27 refs.)

- 78638 Climatic clusters of the Indian region. S.Gadgil, N.V.Joshi (Centre for Theoretical Studies, Indian Inst. of Sci., Bangalore, India). *J. Climatol. (GB)*, vol.3, no.1, p.47-63 (Jan.-March 1983). Derives climatic clusters of the Indian region using monthly mean profiles of the precipitation, the moisture index and the minimum temperature. The delineation of regions over which the profile patterns of important climatic factors are similar is necessary for the determination of meteorological zones over which prediction can be made as well as for understanding the distribution of vegetation cover. The latter has been the major aim of the studies of climatic classification. The variation of the climatic patterns over the Indian region is analysed to obtain climatic clusters, which represent natural grouping of the patterns and hence of the meteorological stations at which they occur, as well as the climatic boundaries separating these clusters. This analysis is facilitated by an initial reduction of the mean monthly profiles of the moisture index are obtained. (24 refs.)

- 78639 Modelling climate and the nature of climate models: a review. K.P.Shine, A.Henderson-Sellers (Dept. of Geography, Univ. of Liverpool, Liverpool, England). *J. Climatol. (GB)*, vol.3, no.1, p.81-94 (Jan.-March 1983). A new structural framework for climate models is presented. Four basic types are discussed: general circulation models, energy balance models, one dimensional radiative convective models and two dimensional zonally averaged dynamical models. The fundamental importance of three primary processes in the climate system-radiation, dynamics and surface processes—is underlined and the degree to which each of these mechanisms is incorporated in each model is highlighted. (80 refs.)

- 78640 Climatic influence of background and volcanic stratosphere aerosol models. P.Y.Deschamps, M.Herman, J.Lenoble, D.Tanre (Lab. d'Optique Atmospherique, Univ. des Sci. et Tech. de Lille, Villeneuve d'Ascq, France). *Adv. Space Res. (GB)*, vol.2, no.5, p.171-6 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).

- A simple modelization of the Earth atmosphere system including tropospheric and stratospheric aerosols is derived and tested. Analytical expressions are obtained for the albedo variation due to a thin stratospheric aerosol layer. Also outlined are the physical procedure and the respective influence of the main parameters: aerosol optical thickness, single scattering albedo and asymmetry factor, and sublayer albedo. The method is applied to compute the variation of the zonal and planetary albedos due to a stratospheric layer of background H₂SO₄ particles and of volcanic ash. (6 refs.)

- 78641 Mid-latitude model analysis of solar radiation, the upper layers of the sea, and seasonal climate. T.P.Charlock (Nat. Center for Atmospheric Res., Boulder, CO, USA). *J. Geophys. Res. (USA)*, vol.87, no.C11, p.8923-30 (20 Oct. 1982). [received: May 1983]

- A simplified, time-dependent energy balance climate model is run at the latitude belt 40°-50°N. The model solves for the temperatures of the land, air, and 12 vertical oceanic layers, and it includes a wind stirred mixed layer. Because the attenuation of solar radiation in the model ocean varies significantly with wavelength in the visible, fine wavelength resolution radiative transfer for Rayleigh scattering and ozone absorption is used between 340 and 720 nm. The optical properties of the model clouds are functions of the cloud liquid water contents. A change in model ocean optical turbidity from relatively clear (Jerlov I) to particle rich (Jerlov III) conditions decreases the effective thickness of the oceanic layer in which heat is stored seasonally and increases the seasonal variation of sea surface temperature by 2°-3°C. (45 refs.)

- 78642 Relation between the changes of clay mineralogy in the cores of marine deposits and the paleoclimatic vicissitudes. He Liangbiao (First Inst. of Oceanography, Nat. Bur. of Oceanography, Qingdao, China). *Kexue Tongbao (Foreign Lang. Ed.) (China)*, vol.28, no.2, p.232-6 (Feb. 1983).

- With respect to the relation between the changes of clay mineralogy in the cores of marine deposits and the paleoclimatic vicissitudes, two completely different viewpoints prevail in the international circles today. One holds that paleoclimatic vicissitudes might be indicated by the changes of clay mineralogy in the cores. The other holds that it has nothing to do with the changes of clay mineralogy. Based on the comprehensive qualitative and quantitative analyses on clay minerals in two cores from the Pacific and in eight cores from the Huanghai Sea, and the data obtained by his colleagues from corresponding cores, the author deems that the changes of clay minerals in the cores, especially those of dominant clay minerals, exhibit a close relationship with the paleoclimatic vicissitudes. This fact gives a strong support to the first viewpoint. (4 refs.)

92.65 ATMOSPHERIC OPTICS

(see also 42.00 Optics)

- 78643 Instantaneous integrated Raman scattering. S.Egert, A.Cohen (Hebrew Univ. of Jerusalem, Jerusalem, Israel), M.Kleiman, N.Ben-Yosef. *Appl. Opt. (USA)*, vol.22, no.10, p.1592-7 (15 May 1983). Lidar detection of atmospheric molecules using a Raman scattering technique being usually limited by low signals is enhanced by integration of the forward Raman scattered light over a large atmospheric volume. This integral can be measured instantaneously in the presence of a reflector at one edge of the optical path, increasing the SNR by a factor of 100 in the case of a perfect reflector and a beam path of ~2 km. Natural reflectors such as clouds leading to the same effect are also discussed. (12 refs.)

78644 On the influence of rough water surfaces on polarimetric investigations of aerosols from space. T.Prosch, D.Hennings, E.Raschke (Inst. für Geophys. und Meteorologie, Univ. zu Köln, Köln, Germany). *Adv. Space Res. (GB)*, vol.2, no.5, p.33-8 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982). The equation of radiative transfer is solved for the complete Stokes's vector in order to study the polarization of solar radiation on top of a turbid atmosphere. Results of surface model calculations are compared with polarimeter measurements. (7 refs.)

78645 Retrieval of aerosol optical characteristics from polarization measurements of reflected solar radiation above the oceans. R.Santer, M.Herman, J.Lenoble (Lab. d'Optique Atmosphérique, Univ. des Sci. et Tech. de Lille, Villeneuve d'Ascq., France). *Adv. Space Res. (GB)*, vol.2, no.5, p.65-70 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982). The reflected near infrared solar radiation observed from space above the oceans is due mainly to atmosphere scattering, as the ocean surface is nearly black. The molecular Rayleigh contribution is also minimized at infrared wavelengths and can be evaluated. It is shown that the degree of polarization is much more sensitive to the aerosol properties than the radiance. Measurements of polarization at two wavelengths and with angular scanning are simulated and an inversion algorithm is proposed. An 'equivalent aerosol model' reproduces the optical thickness and the asymmetry factor of the actual aerosol at all wavelengths in the solar spectrum. (9 refs.)

78646 Aerosol measurements from Earth orbiting spacecraft. M.P.McCormick (Atmospheric Sci. Div., NASA Langley Res. Center, Hampton, VA, USA). *Adv. Space Res. (GB)*, vol.2, no.5, p.73-86 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982). Since the fall of 1978, two Earth-orbiting spacecraft sensors, SAM II (Stratospheric Aerosol Measurement II) and SAGE (Stratospheric Aerosol and Gas Experiment), have been monitoring the global stratospheric aerosol. These experiments use the Sun as a source to make Earth-limb extinction measurements during each spacecraft sunrise and sunset. This paper describes the global aerosol data base that is evolving. Seasonal and hemispheric variations such as the springtime layer expansion with warming temperatures and the local wintertime polar stratospheric clouds are described. The detection and tracking of a number of volcanoes whose effluents penetrated the tropopause are also described. (10 refs.)

78647 Remote monitoring of aerosols from space. O.A.Avaste, S.H.Keevallik (Inst. of Astrophys. & Atmospheric Phys., Acad. of Sci., Tartu, Estonian SSR). *Adv. Space Res. (GB)*, vol.2, no.5, p.87-93 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982). Using the four-channel tele-radiometer 'Micron' aboard Salyut-4 and Salyut-6 the brightness profiles were determined in the near-infrared spectral region up to a height of 60 km (noctilucent clouds up to 80-85 km). Information on the global and vertical distributions of atmospheric aerosol, water vapour concentration and the optical properties of the noctilucent clouds has been obtained. (12 refs.)

78648 Investigation of the atmospheric aerosols by the visible and IR channels of the AVHRR radiometer on NOAA-6. T.Takashima, Y.Takayama (Meteorological Res. Inst., Tsukuba, Japan). *Adv. Space Res. (GB)*, vol.2, no.5, p.95-104 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982). The diffusely reflected radiation in the daytime and diffusely transmitted radiation at night from an inhomogeneous, plane parallel planetary atmosphere bounded by the ocean surface are calculated for the visible and IR region. In the daytime the effect of the solar radiation from the top is taken into account. The present study deals with the problem of no cloud contamination in data. Water vapor, molecular nitrogen, nitrous oxide, carbon dioxide and methane are taken as absorbent constituents and aerosols as the scattering constituent. (3 refs.)

78649 Different atmospheric effects in remote sensing of uniform and nonuniform surfaces. Y.J.Kaufman, R.S.Fraser (Goddard Lab. for Atmospheric Sci., NASA/Goddard Space Flight Center, Greenbelt, MD, USA). *Adv. Space Res. (GB)*, vol.2, no.5, p.157-55 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982). The atmospheric effect on the radiance of sunlight scattered from the Earth-atmosphere system is greatly dependent on the surface reflectance pattern, the contrast between adjacent fields, and the optical properties of the atmosphere. In addition, the atmospheric effect is described by the range and magnitude of the adjacency effects, the atmospheric modulation transfer function and the apparent spatial resolution of remotely sensed imagery. This paper discusses the atmospheric effect on classification of surface features and shows that surface nonuniformity can be used for developing procedures to remove the atmospheric effect from the satellite imagery. (23 refs.)

78650 The characterization of atmospheric spread functions affecting satellite remote sensing of the Earth's surface. R.W.L.Thomas (EG&G Washington Analytical Services Center Inc., Riverdale, MD, USA). *Adv. Space Res. (GB)*, vol.2, no.5, p.157-66 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982). A Monte Carlo simulation program has been used to compute the signal contribution of surface elements outside the field of view of a satellite borne sensor in both the visible and infrared spectra for realistic atmospheric models. For azimuthally symmetric reflection the effect of an arbitrary surface albedo pattern can be represented by two spread functions, namely, the ground-satellite spread function, and the ground-ground spread function. Examples of computed spread functions are shown together with their Fourier correspondents, the modulation transfer functions. It has been shown that the central portions of the line spread functions behave as the inverse distance while the point spread functions always possess a region behaving as the inverse square of the radial distance. (15 refs.)

78651 A method for estimating cross radiance. D.Spankuch (Meteorological Service of Germany, Meteorological Main Obs., Potsdam, Germany), I.Laszlo.

Adv. Space Res. (GB), vol.2, no.5, p.167-70 (1982). [received: April 1983] (Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982). When imaging the surface from satellites or aircraft, 'cross radiance' diminishes the information content of the pictures. A simple method is presented to estimate the value of cross radiance. This method includes a height-dependent aerosol size distribution model and the calculations refer to the single scattering approximation. The height variation of aerosol size distribution has significant effect on the value of cross radiance, while the areal distribution does not change much in comparison with that of the height-independent aerosol model. (4 refs.)

78652 O₂ absorption cross sections (187-225 nm) from stratospheric solar flux measurements. J.R.Herman, J.E.Mentall (NASA/Goddard Space Flight Center, Greenbelt, MD, USA). *J. Geophys. Res. (USA)*, vol.87, no.C11, p.8967-75 (20 Oct. 1982). [received: May 1983]

The absorption cross sections of molecular oxygen are calculated in the wavelength range from 187 to 230 nm from solar flux measurements obtained within the stratosphere. Within the Hertzberg continuum wavelength region the molecular oxygen cross sections are found to be about 30% smaller than the laboratory results of Shardanand and Rao (1977) from 200 to 210 nm and about 50% smaller than those of Hasson and Nicholls (1971). The effective absorption cross sections of O₂ in the Schumann-Runge band region from 187 to 200 nm are calculated and compared to the empirical fit given by Allen and Frederick (1982). The calculated cross sections indicate that the transmissivity of the atmosphere may be underestimated by the use of the Allen and Frederick cross sections between 195 and 200 nm. (14 refs.)

78653 Modeling the isotope composition of oxygen in the ancient atmosphere of the Earth. V.N.Melenevskii (Sci. Res. Inst. of Geology, Geophysics, & Mineral Raw Materials, Novosibirsk, USSR).

Sov. Geol. & Geophys. (USA), vol.23, no.3, p.17-23 (1982). Translation of: *Geol. & Geophys. (USSR)*, vol.23, no.3, p.23-9 (1982). From data on fractionation of oxygen isotopes and theories of the intensity of photosynthesis on the continents and in the World Ocean, a quantitative estimate is made of the balance of oxygen isotopes for the modern biosphere. The authors discuss the major factors which could have influenced the oxygen isotope composition of the Earth's ancient atmosphere. (42 refs.)

93.85 INSTRUMENTATION AND TECHNIQUES FOR GEOPHYSICAL RESEARCH

- 78654** Determination of phosphorus in natural waters by long-capillary-cell absorption spectrometry. Wei Lei, K.Fujiwara, K.Fuwa (Dept. of Chem., Univ. of Tokyo, Tokyo, Japan). *Anal. Chem. (USA)*, vol.55, no.6, p.951-5 (May 1983).
Use of a long capillary cell (LCC) effectively enhances the detection power of ordinary colorimetry. The minimum necessary volume of sample is about 1-3 mL. By application of this method to molybdenum-blue colorimetry, 5 pg/mL of phosphorus is detectable. Phosphorus concentrations less than 1 ng/mL in seawater and lake water are successfully determined by using LCC. The advantages of LCC are low cost of construction, simple manipulation, and high stability of obtained signal. Theoretical and experimental aspects of LCC are discussed. (13 refs.)
- 78655** Applications of an orbiting gravity gradiometer. O.L.Colombo (Inst. for Phys. Geodesy, Tech. Univ. of Darmstadt, Darmstadt, Germany), A.Kleusberg. *Bull. Geod. (France)*, vol.57, no.1, p.83-101 (1983).
Considering present attempts to develop a gradiometer with an accuracy between 10^{-3} E and 10^{-6} (1E, or Eotvos unit is 10^{-9} s⁻²), two applications for such a device have been studied: (a) mapping the gravitational field of the Earth and (b) estimating the geocentric distance of a satellite carrying the instrument. A simulation study based on numerical orbit integrations suggests that a simple adjustment of the initial conditions based on gradiometer data could produce orbits where the geocentric distance is accurate to 10 cm or better, provided the orbits are 2000 km high and some improvement in the gravity field up to degree 30 is first achieved. (14 refs.)
- 78656** Frost mapping in southern Victoria: an assessment of HCMM thermal imagery. J.D.Kalma, G.F.Byrne, M.E.Johnson (Inst. of Biological Resources, CSIRO, Canberra, Australia), G.P.Laughlin. *J. Climatol. (GB)*, vol.3, no.1, p.1-19 (Jan.-March 1983).
HCMM satellite thermal imagery is used in a detailed frost assessment in an important horticultural area near Melbourne, Australia. Good general agreement is found to exist between plots based on night-time HCMM data which show surface temperature differences across the study area and frost risk maps based on terrain and land cover. However, it is concluded that the HCMM data have insufficient spatial resolution for use in local frost mapping in the study area. Improved thermal resolution will make thermal imagery from future satellites an increasingly important tool in topoclimatology. Without such improvements local frost mapping will, in the absence of climatic network data or mobile topoclimatological surveys, continue to depend on data from thermal scanners in aircraft and on detailed assessment of terrain and land cover. (30 refs.)
- 78657** Passive remote sensing of aerosols from space now and in the future. H.Quenzel (Meteorologisches Inst., Univ. Munchen, Munchen, Germany). *Adv. Space Res. (GB)*, vol.2, no.5, p.19-28 (1982). [received: April 1983]
(Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).
Aerosols modify scattered solar radiation leaving the atmosphere and this fact can be exploited to determine the aerosol optical depth. The interaction processes between solar radiation and aerosol particles are outlined. A quasi-linear relationship ('conversion curves') between the radiance at the satellite, L_{sat} , and the aerosol optical depth, $a_{p\lambda}$, is found from both numerical and empirical studies. Because L_{sat} is not only controlled by a p_{λ} , but also by a series of other atmospheric parameters (perturbing quantities), the concept of 'favourable viewing conditions' is presented, where the effects of the perturbing quantities are minimal. The paper ends with some lines of thought on a concept for a turbidity satellite. (16 refs.)

- 78658** Most suitable conditions for aerosol monitoring from space. P.Kopke, H.Quenzel (Meteorological Inst., Univ. of Munich, Munich, Germany). *Adv. Space Res. (GB)*, vol.2, no.5, p.29-32 (1982). [received: April 1983]
(Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).
Favorable zenith angles of the satellite and favorable wavelengths are presented for an atmosphere with maritime aerosols with and without Saharan dust. (8 refs.)
- 78659** Laser sounding of aerosols using airborne and space facilities. V.E.Zuev (Inst. of Atmospheric Optics, Acad. of Sci., Tomsk, USSR). *Adv. Space Res. (GB)*, vol.2, no.5, p.39-47 (1982). [received: April 1983]
(Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).
Presents the results of sounding of water droplet crystal and mixed clouds carried out using an airborne lidar. A new method of determining the phase state of a cloud is described. The results are given on numerical experiments of laser sounding of various clouds using a polarization lidar. Numerical simulation of laser sounding of aerosols from space for different lidar parameters and geometrical schemes of sounding is carried out using new models of aerosol vertical profiles. (11 refs.)
- 78660** Spaceborne lidar measurement accuracy: simulation of aerosol, cloud, molecular density, and temperature retrievals. P.B.Russell, B.M.Morley (SRI Internat., Menlo Park, CA, USA), E.V.Browell. *Adv. Space Res. (GB)*, vol.2, no.5, p.49-53 (1982). [received: April 1983]
(Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).
Spaceborne lidar measurements and retrievals are simulated using realistic errors in signal, conventional density information, atmospheric transmission, and lidar calibration. To reduce molecular-density uncertainties and also to provide density and temperature profiles, a procedure that combines returns at 0.35 and 1.06 μ m is developed. This technique significantly improves UT/NVS aerosol retrieval accuracy and also yields useful density and temperature profiles. Strong particulate contamination limits the technique to the cloud-free upper troposphere and above. (5 refs.)
- 78661** Retrieval of aerosol characteristics from scattering and extinction measurements. A.Deepak, P.-H.Wang (Inst. for Atmospheric Optics & Remote Sensing, Hampton, VA, USA). *Adv. Space Res. (GB)*, vol.2, no.5, p.55-64 (1982). [received: April 1983]
(Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).
A versatile inversion code has been developed which is capable of retrieving profiles of aerosol size distribution and concentration from multi-wavelength measurements of either the scattered radiance from the Earth's sunlit atmosphere in both the limb-viewing mode and downward-viewing mode, or the extinction of direct solar radiation by the Earth's atmosphere. The inversion code in its present form is a composite of three sub-codes corresponding to the three measurement modes. A description of these codes is given and results of retrievals are discussed. (5 refs.)
- 78662** Validation of aerosol measurements by the satellite sensors SAM II and SAGE. P.B.Russell (SRI Internat., Menlo Park, CA, USA), M.P.McCormick, T.J.Swisher. *Adv. Space Res. (GB)*, vol.2, no.5, p.123-6 (1982). [received: April 1983]
(Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).
The satellite sensors SAM II and SAGE have been developing a global data base on stratospheric aerosols since they were launched in October 1978 and February 1979, respectively. The validity of this data base is tested by numerous comparisons with other measurements made by lidars, balloon-borne particle counters, and aircraft-borne impactors and filters. Because the satellite sensors measure extinction and the correlative sensors measure other properties, special techniques are required to convert each measured property to other properties and to quantify conversion uncertainties and measurement uncertainties. Use of these techniques in two major comparative experiments shows that the SAM II and SAGE extinction measurements agree with each other and with values derived from dustsonde, lidar, and filter measurements. (6 refs.)
- 78663** Retrieval of aerosol size distribution from extinction measurements and verification with observations at a tropical station. P.Sikka, R.Vijayakumar, A.M.Selvan, Bh.V.R.Murty (Indian Inst. of Tropical Meteorology, Pune, India). *Adv. Space Res. (GB)*, vol.2, no.5, p.127-9 (1982). [received: April 1983]
(Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).
Aerosol size distributions are retrieved by computing aerosol extinction parameters using extensive measurements of direct solar radiation made in the 0.4 and 0.6 μ m wavelengths at Pune with a Volz type sunphotometer during winter (November-February), pre-monsoon (March-May), monsoon (June-August) and post-monsoon (September-October) seasons of 1980-81. The computed aerosol size distributions are compared with the direct measurements made using Anderson eight-stage cascade impactor. The retrieval method is simple and useful for intensive aerosol measurement programmes. (3 refs.)
- 78664** Determination of aerosol optical depth from ground measurements. C.Frohlich (Phys.-Meteorologisches Obs., World Radiation Center, Davos, Switzerland). *Adv. Space Res. (GB)*, vol.2, no.5, p.139-45 (1982). [received: April 1983]
(Proceedings of the Topical Meeting of the COSPAR Interdisciplinary Scientific Commission A (Meetings A1 and A2) of the COSPAR Twenty-Fourth Plenary Meeting, Ottawa, Canada, 16 May-2 June 1982).
The methods used to determine the aerosol optical depth as a function of wavelength are briefly described and discussed. Some results from the operational network of the World Meteorological Organization and other, more research oriented studies, are reviewed and critically analysed to assess the reliability and accuracy of such determinations and their value as ground truth measurements for space applications. (13 refs.)
- 78665** Recent developments in ion mass spectrometers in the energy range below 100 keV. H.Balsiger (Phys. Inst., Univ. of Bern, Bern, Switzerland). *Adv. Space Res. (GB)*, vol.2, no.7, p.3-11 (1982).
The recognition that heavy ions often have similar or higher abundance than protons in space plasmas and the fact that ions with masses and/or charges larger than unity are ideally suited to test theories on origin, transport, acceleration, and loss of these plasmas led to the development of new and

more sophisticated mass spectrometers during the last decade. The characteristics of several state-of-the-art instruments which have been flown or selected for missions are discussed and aims for future developments given. (19 refs.)

78666 Some recent advances in energetic ion mass spectrometry. B.A. Whalen (Herzberg Inst. of Astrophys., Nat. Res. Council of Canada, Ottawa, Ontario, Canada).

Adv. Space Res. (GB), vol.2, no.7, p.13-20 (1982).
New techniques are being developed which will extend the capability of spacecraft-borne ion mass spectrometers into previously unexplored momentum regimes. These instruments include time-of-flight mass spectrometers and large laboratory class spectrometers suitable for spacelab applications. Their characteristics, strengths and weaknesses are reviewed. (6 refs.)

78667 Spherical ion traps for 'INTERCOSMOS-BULGARIA-1300'. T.N.Ivanova (Central Lab. for Space Res., Bulgarian Acad. of Sci., Sofia, Bulgaria), T.D.Samardjiev, S.M.Halova, P.T.Kostov, G.S.Karamishev, I.S.Kutiev, G.L.Gdalevich.

Adv. Space Res. (GB), vol.2, no.7, p.21-5 (1982).
Describes the P6-IT device for investigating the ion composition of the ionospheric plasma. The device is necessary for the study of the complex dynamic behaviour of the plasma, the interaction of the ionosphere and the magnetosphere, and the global distribution of charged particles. The P6-IT is composed of two spherical sensors and an electronic unit. This paper discusses the working characteristics of the instrument and gives, as a sample, the ion distribution along orbit number 175. (7 refs.)

78668 The ion energy and mass analyzer on board the 'INTERCOSMOS-BULGARIA-1300' satellite. P.Nenovski, Y.Semkova, R.Koleva, S.Chapkunov, N.Kanchev, N.Tabov, A.Kanchev, O.Valsberg, V.Smirnov, G.Zastenker, A.Leibov (Central Lab. for Space Res., Bulgarian Acad. of Sci., Sofia, Bulgaria).

Adv. Space Res. (GB), vol.2, no.7, p.27-30 (1982).
An original instrument for ion energy distribution measurement in ionospheric plasma above the F-layer was designed and launched on board the INTERCOSMOS-BULGARIA-1300 satellite. The instrument performs differential energy analysis of ion species within the two energy ranges of 1-27 eV/q and 0.2-8 keV/q. (5 refs.)

78669 An instrument for DC electric field and AC electric and magnetic field measurements aboard 'INTERCOSMOS-BULGARIA-1300' satellite. G.Stanev, M.Petrunova, D.Teodosiev, I.Kutiev, K.Serafimov, S.Chapkunov, V.Chmyrev, N.Isaev, P.Puschae, I.Pimenov, S.Bilichanko (Central Lab. for Space Res., Bulgarian Acad. of Sci., Sofia, Bulgaria).

Adv. Space Res. (GB), vol.2, no.7, p.43-7 (1982).
The instrument IESP-IPMP represents a complex unit measuring the vector of the DC electric field, the vectors of the electric and magnetic field in the frequency range of 0.2-6.5 Hz (wave form), autocorrelation functions of waves with frequencies of 0.1-5 kHz, and wave amplitudes in eight bandpass channels. Some results are shown and compared in the various frequency ranges. (9 refs.)

78670 Field and wave measurements aboard the Aureol-3 spacecraft. J.J.Berthelier (LGE, CNRS, St. Maur, France), A.Berthelier, Yu.I.Galperin, V.A.Gladyshev, F.Lefevre, N.I.Massevitch, M.Mogilevsky, O.A.Molchanov.

Adv. Space Res. (GB), vol.2, no.7, p.49-52 (1982).
In the Soviet-French Arcad-3 project, 3 experiments TBF-ONCH, TRAC and ISOPROBE are carried out on board the Aureol-3 satellite to measure the AC and DC electric and magnetic fields and waves. Several modes of telemetry, real time and memory regimes are available for data transmission. Examples of inflight measurements from the above instruments and their presentation on microfiches are shown. Some new phenomena are emphasized and briefly discussed. (12 refs.)

78671 The resonance cone technique for exciting electron acoustic waves in equatorial ionosphere. S.P.Gupta (Phys. Res. Lab., Ahmedabad, India).

Adv. Space Res. (GB), vol.2, no.7, p.87-8 (1982).
A rocketborne radio frequency resonance cone technique is discussed. The technique is ideal over the geomagnetic equator where the Earth's magnetic field is horizontal. The radio frequency exciter is fixed along the axis of the rocket. By measuring the semi-angle of this cone various plasma parameters can be derived, such as electron density and temperature. (3 refs.)

78672 A retarding potential analyser for rocket experiments. B.Kirov (Central Lab. for Space Res., Bulgarian Acad. of Sci., Sofia, Bulgaria), K.Georgieva, E.Apostolov, M.Gusheva, I.Kutiev, S.Chapkunov, Yu.Simeonova.

Adv. Space Res. (GB), vol.2, no.7, p.89-92 (1982).
A retarding potential analyzer is designed using a micro-channel plate in front of the collector as a flow amplifier, which makes it possible to detect ion species with very low concentration ($<0.5 \text{ cm}^{-3}$). A technique is described for using the micro-channel plate at abnormally high pressure ($>0.01 \text{ N/m}^2$). This allows the precise determination of the mass composition of the low ionosphere. An adaptive retarding potential consisting of 2048 steps is used to increase the sensitivity. The sensor is hermetically sealed and opens on command. (4 refs.)

78673 Measurements of the energy spectra of charged particles within the VERTICAL-10 rocket experiment. I.Ivanov, Ts.Dachev, Yu.Matviichuk, D.Krezhova, D.Gochev, I.Rumchev (Central Lab. for Space Res., Bulgarian Acad. of Sci., Sofia, Bulgaria).

Adv. Space Res. (GB), vol.2, no.7, p.93-5 (1982).
The 21 December 1981 'VERTICAL-10' payload included a low-energy two-channel spectrometer for measuring the differential flows of electrons and the protons within the energy range 0.1 to 10 keV, covered by 15 exponentially distributed energy levels. The device was installed so as to measure the electron flows in the direction of movement of the scientific payload container and to determine proton flows perpendicular to it. (no refs.)

78674 Digital processing of Spacelab imagery. P.Muralikrishna, S.Prakash, B.H.Subbaraya (Phys. Res. Lab., Ahmedabad, India).

Adv. Space Res. (GB), vol.2, no.7, p.107-10 (1982).
A digital technique for processing and analyzing OH-cloud photographs to be retrieved from the ISRO-CNES collaborative experiment on the first Spacelab is presented and discussed. The method adopted for processing the photographs incorporates the following major steps (i) digitising the OH photographs, (ii) applying corrections for vignetting, geometric distortions and brightness variations and (iii) superimposing the geographical coordinates on the linearised OH photograph. (2 refs.)

78675 WAMDIH—a wide angle Michelson Doppler imaging interferometer for Spacelab. W.A.Gault, G.G.Shepherd (Centre for Res. in Experimental Space Sci., York Univ., Toronto, Ontario, Canada).

Adv. Space Res. (GB), vol.2, no.7, p.111-14 (1982).
A CCD imaging device has been designed which combines a spatial resolution of $0.1''$ with a spectral resolving power of 10^5 , sufficient to measure doppler shifts and line widths of individual atmospheric emission lines. It will be

flown aboard Spacelab and will be used to study neutral winds and temperatures as functions of height, latitude and time of day. (6 refs.)

78676 Airglow atmospheric imager on board the 'IK-BULGARIA-1300' satellite. M.Gogoshev (Central Lab. for Space Res., Bulgarian Acad. of Sci., Sofia, Bulgaria), N.Petkov, A.Kuzmin, Ts.Gogosheva, St.Spassov, Iv.Kostadinov.

Adv. Space Res. (GB), vol.2, no.7, p.115-20 (1982).
Shows the possibilities of the optical scanning imager for investigation of the structure of the auroral, SAR and tropical arcs and in this way to study the particle precipitation, neutral winds across the magnetic equator, drifts, electric fields and the current systems in the ionosphere. (15 refs.)

78677 Measurement of electric fields in the ionosphere by incoherent scatter radar techniques. T.Hagfors (EISCAT Sci. Assoc., Kiruna, Sweden), J.Silen.

Adv. Space Res. (GB), vol.2, no.7, p.121-9 (1982).
Various methods for the extraction of electric fields from incoherent scatter radar observations are discussed. The random errors in electric field determinations are derived and it is shown that under typical conditions observations such as EISCAT should measure electric fields with an r.m.s. error of about 1 mV/m with one minute integration time. Some preliminary EISCAT results are shown and compared with other observations. (4 refs.)

78678 BARS—a dual bistatic auroral radar system for the study of electric fields in the Canadian sector of the auroral zone. A.G.McNamara (Nat. Res. Council, Ottawa, Ontario, Canada), D.R.McDiarmid, G.J.Sofko, J.A.Koehler, P.A.Forsyth, D.R.Moorcroft.

Adv. Space Res. (GB), vol.2, no.7, p.145-8 (1982).
One instrument of the Canadian Auroral Network for the Open Program Unified Study (CANOPUS) is a pulsed dual bistatic auroral radar system (BARS) for the mapping of ionospheric electric fields, using the STARE technique. The Canadian system is presently in the specification and design phases, with the objective of being operational by mid-1984. This paper describes the geometry of the BARS system, the design considerations, and the planned data and control network. (17 refs.)

78679 Interactive analysis of magnetic field data. C.T.Russell (Inst. of Geophys. & Planetary Phys., Univ. of California, Los Angeles, CA, USA).

Adv. Space Res. (GB), vol.2, no.7, p.173-6 (1982).
A pair of programs, entitled BANAL and TANAL, have been created in the UCLA Space Sciences Group for the interactive analysis of magnetic field data. These programs reduce the time from the inception of an idea to its testing, and thereby enhance both the productivity and creativity of the user. They accomplish this through menu-driven procedures for the display and analysis of time series data, including Fourier analysis. Cursor selection of subsections of the data for entry into the analysis procedures as well as automatic scaling minimize the required keyboard input from the user. (3 refs.)

78680 Ionospheric plasma parameters measurement instrument for satellite experiment with SIT. T.N.Ivanova, S.M.Halova, P.T.Kostov, G.S.Karamishev (Central Lab. for Space Res., Bulgarian Acad. of Sci., Sofia, Bulgaria).

C.R. Acad. Bulg. Sci. (Bulgaria), vol.36, no.1, p.81-4 (1983).
Describes the measurement of the ionic plasma parameters (concentration of ions N_i , temperature T_i , mass composition M_i and energy distribution E_i), as well as of the electron concentration, temperature and energy, by means of a complex scientific apparatus mounted on the Interkosmos Bulgaria-1300 satellite, which makes it possible to analyse a number of physical parameters connected with the heat balance and the dynamic processes in the ionosphere. The P6-SIT instrument was designed for the measurement of the above ion parameters by means of three- and four-electrode spherical ion traps (SIT). (6 refs.)

78681 Statistical techniques using NURE airborne geophysical data and NURE geochemical data. K.Campbell (Los Alamos Nat. Lab., Los Alamos, NM, USA).

Comput. & Geosci. (GB), vol.9, no.1, p.17-21 (1983). (First Annual Conference on 'The Management, Analysis, and Display of Geoscience Data', Golden, CO, USA, 27-29 Jan. 1982).
Some standard techniques in multivariate analysis are used to describe the relationships among remotely sensed observations (Landsat and airborne geophysical data) and between these variables and hydrogeochemical and stream sediment analyses. Gray-level pictures of such factors make the analytic results more accessible and easier to interpret. (no refs.)

78682 Thermal fading of fission tracks at variable temperature: applications to geochronology. Y.Cantelaube (Lab. de Mineralogie, Museum d'Histoire Naturelle, Paris, France).

Nucl. Tracks & Radiat. Meas. (GB), vol.6, no.4, p.143-60 (1982).
The Arrhenius law is extended to the case when the fading temperature varies over time. The proposed equation is induced from the Arrhenius equation, independently of any representative function of some track-fading parameter, and without taking into account any of the usual track-annealing models. The author uses r_i -diagrams to plot plateau-age curves. A simple method is deduced to discriminate between previously affected and unaffected fossil-track populations, by using track-density data of the plateau-age technique. The onset of the last fission-track storage and the end of the last partial track-fading, and therefore the average track-fading rate corresponding to this time interval, can thus be determined. Values of affected and unaffected fossil-track populations are compared with those which have been obtained by other methods. (9 refs.)

78683 A new etching technique for developing fission tracks in epidote. A.B.Chakranarayan, K.B.Powar (Dept. of Geology, Univ. of Poona, Pune, India).

Nucl. Tracks & Radiat. Meas. (GB), vol.6, no.4, p.193-5 (1982).
The authors present the results of etching epidotes from skarn rocks from Belka Pahar, Rajasthan, India. They were etched in both NaOH and HF under varying conditions of temperature, time, and etchant concentration, but tracks were only revealed by etching with 25N NaOH for 1 to 2 hours at 15°C and then with 45% HF for 15 minutes at room temperature. (7 refs.)

78684 A filtering procedure for great circle data. A.Souriau, M.Souriau (Centre Nat. d'Etudes Spatiales, Groupe de Recherches de Geodesie Spatiale, Toulouse, France).

Ann. Geophys. (France), vol.1, no.1, p.7-10 (Jan.-Feb. 1983).
Proposes a filtering method which applies to great circle data, i.e. to data which represent the integral, along great circles, of a function defined at each point of the sphere. This filter is based on the vanishing of the odd harmonics in the global spherical harmonic expansion of great circle values. This filter also enables to obtain a lower estimate of the S/N ratio in the data using a comparison with synthetic data. The authors present two examples relevant to seismological data. (3 refs.)

78685 Recovery of reflector series by determining the beginning position of estimated wavelets using short-time homomorphic analysis. J.Y. Kim, J. Behrens (Inst. für Angewandte Geophys., Petrologie und Lagerstättenforschung, Tech. Univ. Berlin, Berlin, Germany).

Ann. Geophys. (France), vol.1, no.1, p.11-15 (Jan.-Feb. 1983).
The use of cepstral gating to estimate the reflector series directly has led sometimes to erroneous results, especially in the fine structure investigations. In addition, it should be noted that the estimated sequences are in general uniformly time-delayed. It is mainly due to cepstral disturbances caused by mixed-delay reflector series, time-varying character of source signal and additive noise. The author discusses recovering the reflector series by determining the beginning position of the estimated wavelets. The paper is based on the short-time homomorphic analysis comprising a number of windows. This technique is illustrated by means of both synthetic and real data. (10 refs.)

78686 Seismic transducers: noise suppression and prevention in the piezoelectric transduction systems. C. Parmigiani.

Elettrom. Oggi (Italy), no.2, p.173-80 (Feb. 1983). In Italian.
Noise generation mechanisms in seismic instrumentation are analysed. Suppression and prevention methods are suggested. Capacitive and electromagnetic couplings are discussed detailing isolating amplifier connection modes and circuit arrangements. Piezoelectric transducer connection circuitry configurations are shown comparing various systems operations. The main recommendations include usage of low noise coaxial cables, single point earth connection, isolation of adjacent cables, amplification and instrument selection. (no refs.) T.H.

78687 Seismic transducers: calibration systems. C. Parmigiani.

Elettrom. Oggi (Italy), no.3, p.209-20 (March 1983). In Italian.
Seismic transducer calibration system and standards are reviewed. Reciprocity calibration method (Bouche-Levy) is analysed highlighting accuracy grades and test procedures. Reference standards are discussed detailing frequency response calibration. Frequency responses under various conditions are considered quoting numerous response curves. Shock response tests are detailed showing test procedures and an error analysis method. (4 refs.) T.H.

78688 A comparison of time and frequency domain geomagnetic sounding. D. Beamish (Inst. of Geological Sci., Edinburgh, Scotland).

Geophys. J. R. Astron. Soc. (GB), vol.73, no.3, p.689-704 (June 1983).
A three-site geomagnetic data set from the Borders region of southern Scotland is used to examine the empirical relationships established by differential geomagnetic sounding experiments. A time domain analysis of such relationships reveals time domain transfer functions which appear to be almost independent of time. A frequency domain analysis is then used to illustrate both a significant phase rotation and a significant dependence on period of the equivalent frequency domain response functions. The formalism of conventional geomagnetic sounding is re-examined. It is found that difference fields are not required to establish the appropriate horizontal field relationships. (17 refs.)

78689 Dielectric logging with downhole invasion effects. J.S. Yu (Sandia Nat. Labs., Albuquerque, NM, USA), P.C. Reardon, P.C. Lyne.

IEEE Trans. Antennas & Propag. (USA), vol.AP-31, no.3, p.397-405 (May 1983).
The transfer impedance between conducting coils is evaluated to estimate the downhole dielectric properties that can contribute to more effective exploration and production of gas/oil reservoirs. The earth formation with a borehole-mud filtrate invasion is simulated by concentric zones of variable dielectric properties to account for rocks saturated by different fluids. The authors have imposed analytical restrictions to allow only magnetic-dipole coupling between logging coils and to limit logging source frequencies from 10 to 30 MHz for typical coil spacings. Depending on the depth of invasion front, guided waves may exist in the invaded formation. When guided waves do not exist, rapidly converging branchcut integrations are used to evaluate the transfer impedance. When the invasion front begins to support guided waves the numerical convergence becomes somewhat slower using spatial-band-limited integrations. Both types of integration are used to produce inversion charts from which dielectric properties and invasion-front radii can be estimated from downhole-measurable transfer impedances. Ambiguity in parameter inversion is also demonstrated to provide insight for developing a future inverse process based on array processing of adequately sampled data. (21 refs.)

78690 Prediction of sites of occurrence of strong earthquakes in large seismicogenic zones of Tadzhikistan. A.S. Malamud, V.K. Kulagin (Inst. of Earthquake Resistant Construction & Seismology, Acad. of Sci., Tadzhik SSR).

Izv. Akad. Sci. USSR, Phys. Solid Earth (USA), vol.18, no.3, p.184-7 (1982). Translation of: *Izv. Akad. Nauk SSSR Fiz. Zemli*, vol.18, no.3 (1982).
A method is described for predicting the sites of occurrence of strong ($M \geq 5.5$) earthquakes by constructing spatiotemporal graphs reflecting the sequence of liberation of seismic energy along large seismicogenic zones. The results obtained confirm a hypothesis that sections which remain vacant a long time are the most likely sites of occurrence of strong earthquakes. A prediction map of such sites on the territory of Tadzhikistan and contiguous regions is constructed. (12 refs.)

78691 Method of quenching functions and its application for determining the singular points of geophysical fields satisfying three-dimensional equations of Laplace and Helmholtz. G.M. Voskoboynikov, A.F. Shestakov (Inst. of Geophys., Acad. of Sci., USSR).

Izv. Akad. Sci. USSR, Phys. Solid Earth (USA), vol.18, no.3, p.207-16 (1982). Translation of: *Izv. Akad. Nauk SSSR Fiz. Zemli*, vol.18, no.3 (1982).

The method of determining the singular points of geophysical field satisfying the equations of Laplace and Helmholtz is discussed with the aid of the quenching function of real variables. The physical and mathematical bases of this method and the principles of constructing computation schemes for determining the coordinates, type, and orientation of the characteristics of the field, are explained. The techniques of compiling initial data for the problem and the prospects for applying the method to the interpretation of basic geophysical fields are discussed. (12 refs.)

78692 A technique for reducing low-frequency, time-dependent errors present in network-type surveys. J.R. Cloutier (US Naval Oceanographic Office, NSTL Station, Bay St. Louis, MS, USA).

J. Geophys. Res. (USA), vol.88, no.B1, p.659-63 (10 Jan. 1983). [received: May 1983]

At each node of a network-type survey, two surveyed values are obtained. In the absence of errors, these two values should be equal, providing that the quantity being surveyed is, for all practical purposes, time independent. When a low-frequency, time-dependent error enters the system, it can be indirectly observed in the form of surveyed-value differences occurring at the network nodes. This paper describes a technique for reducing such an error. The method consists of using a conjugate gradient projection algorithm to find the unbiased, discrete function of minimum weighted variation which produces

the observed nodal differences. After inspecting the discrete solution, a suitably chosen continuous function can be fitted to the discrete data and used to reduce the time-dependent error. This technique has been successfully used to reduce the radial ephemeris error present in SEASAT geoid height data (Cloutier, 1981). (5 refs.)

78693 Optical tracking of synchronous Earth's satellites for geophysical purposes. S. Catalano (Istituto di Astronomia, Univ. di Catania, Catania, Italy), R. McCrosky, A. Milani, A.M. Nobili.

J. Geophys. Res. (USA), vol.88, no.B1, p.669-76 (10 Jan. 1983). [received: May 1983]

Tracking data from synchronous Earth's satellites can be analyzed to provide the resonant geopotential coefficients, mainly C_{22} and S_{22} which represent the ellipticity of the Earth's equator. Geosynchronous satellites currently used for telecommunication purposes can be easily tracked with moderate size large field telescopes measuring the satellite angular coordinates with respect to some catalogue field stars. The accuracy is at least 2 arc sec (≈ 400 m). Optical tracking does not need any onboard device and is easily accomplished. It is concluded that the organization of a worldwide optical tracking campaign would allow an improvement in the knowledge of the long-wavelength geoid by at least one order of magnitude. (24 refs.)

78694 Magnetic polarity stratigraphy: stochastic properties of data, sampling problems, and the evaluation of interpretations. N.M. Johnson, V.E. McGee (Dartmouth Coll., Hanover, NH, USA).

J. Geophys. Res. (USA), vol.88, no.B2, p.1213-21 (10 Feb. 1983).

A statistical model has been derived which can be used either to test the interpretation of a given magnetic stratigraphy or to make time estimates from the paleomagnetic data. The model is based on the presently accepted statistical properties of the Earth's magnetic field and the stochastic nature of the paleomagnetic sampling process. Given knowledge of the number of paleomagnetic sites, the distribution of the sites, an estimate of the geologic time span sampled, and the mean length of the magnetic polarity zones, the expected success of the sampling program can be calculated and compared with its actual performance. The mean time span for polarity intervals in the late Neogene has been established from existing data at 120000 years. Once the mean timespan for polarity intervals has been established, estimates for stratigraphic timespan can be made by means of the statistical model. (17 refs.)

78695 Direct inversion of one-dimensional magnetotelluric data. S. Coen, F. Quercia, M. Mackiewicz (Dept. of Materials Sci. & Mineral Engng., Univ. of California, Berkeley, CA, USA).

J. Geophys. Res. (USA), vol.88, no.B3, p.2407-12 (10 March 1983).

It is shown that the conductivity profile of a layered Earth can be obtained directly (noniteratively) from one-dimensional magnetotelluric observations. The approach used is based on the Born approximation to the electric field integral equation. The inversion algorithm is applied to two data sets. The first one is analytic, and it is possible to show analytically all the steps in the inversion algorithm. The resulting conductivity profile is an adequate approximation to the actual profile. The second data set contains the apparent resistivities from a particular field site at 21 frequencies, and the resulting conductivity profile compares adequately with well log measurements. The results obtained are promising enough to consider the direct inversion of two-dimensional data. (10 refs.)

78696 Condensation sampling of soluble atmospheric trace gases. J.C. Farmer, G.A. Dawson (Inst. of Atmospheric Phys., Univ. of Arizona, Tucson, AZ, USA).

J. Geophys. Res. (USA), vol.87, no.C11, p.8931-42 (20 Oct. 1982). [received: May 1983]

The condensation of water vapor onto a cooled surface can be used as a method of sampling atmospheric components; the method is investigated theoretically and experimentally. From solutions to the heat and mass flow within the convective boundary layer, it is shown that the method has greatest collection efficiency for highly soluble gases. Discrimination against particles and relatively insoluble gases should be excellent. The method is illustrated by some measurements of NH_3 , HNO_3 , HNO_2 , SO_2 , HCl , H_2O , HCHO , HCOOH , and CH_3COOH in the vicinity of Tucson, Arizona. Concentrations are in the part-per-billion range or below. Diurnal variations in these concentrations are discussed. (20 refs.)

78697 Sources of background current in the ECC ozonesonde: implications for total ozone measurements. D.C. Thornton, Nagla Niaz (Dept. of Chem., Drexel Univ., Philadelphia, PA, USA).

J. Geophys. Res. (USA), vol.87, no.C11, p.8943-50 (20 Oct. 1982). [received: May 1983]

The source of the background current in the usual operation of the electrochemical concentration cell ozonesonde is the reduction of tri-iodide (iodine) normally present in the cathode solution. The authors can explain the time variations in the background current by the slow rates of solution mass transport and of heterogeneous electron transfer for tri-iodide. Oxygen does not contribute to the background current through reaction with iodide to produce tri-iodide. Direct reduction of oxygen at the cathode is negligible once the electrodes have been exposed to iodide for 24 hours. The present background current correction is altitude-dependent, since it is based on an assumed sensitivity of the electrochemical concentration cell to oxygen. (13 refs.)

78698 Semiautomatic nondispersive infrared analyzer apparatus for CO_2 air sample analyses. W.D. Komhyr, L.S. Waterman (Air Resources Labs., NOAA, Boulder, CO, USA), W.R. Taylor.

J. Geophys. Res. (USA), vol.88, no.C2, p.1315-22 (20 Feb. 1983). (Symposium on the Rise in Atmospheric Carbon Dioxide, Bern, Switzerland, 14-18 Sept. 1981).

A semiautomatic nondispersive infrared analyzer apparatus has been developed for analysis of up to 50 CO_2 air samples per day. The samples are collected in 500-ml glass flasks and are transferred to the analyzer with a novel, free-floating piston pump. Sample and calibration gas transfer operations are controlled by a microprocessor, and data are recorded, analyzed, and output by a Hewlett-Packard 9845A/S desktop computer. The apparatus is described, including operating and test modes, and performance characteristics determined from 2 years of operation are given. (7 refs.)

78699 Registration of thunderstorm centers by automatic atmospheric stations. H. Volland, J. Schafer, P. Ingmann (Radioastronomisches Inst., Univ. Bonn, Bonn, Germany), W. Harth, G. Heydt, A. J. Eriksson, A. Manes.

J. Geophys. Res. (USA), vol.88, no.C2, p.1503-18 (20 Feb. 1983).

A new generation of VLF-atmospheric receivers and analyzers is presented that operates completely automatically and allows the realtime identification of thunderstorm activity centers. The mean azimuth and angular spread of each thunderstorm center within the detection range as well as the mean statistical properties of three measured spectral parameters of the atmospherics originating at that center are determined within each measuring period (20 min) by a desktop computer. Using a suitable statistical procedure for determining the mean angular and spectral parameters and applying a new extended model for VLF-propagation as function of the solar zenith

angle and of the magnetic field component along the propagation path, the operation program determines in real time the distances and strengths (atmospheres/min) of the activity centers so that all data can be immediately printed out and stored on the internal magnetic tape cartridge. Additionally, an external plotter is used for marketing the thunderstorm centers on a map. (19 refs.)

78700 A new method for measuring radon exhalation. P.Fernandez, L.S.Quindos, J.Soto, E.Villar, D.Guedalia (Dept. of Fundamental Phys., Univ. of Santander, Santander, Spain).

J. Geophys. Res. (USA), vol.88, no.C2, p.1519-24 (20 Feb. 1983).

A method for measuring radon exhalation based on the determination of radon profile into the soil by gamma spectrometry using an ^{137}Cs detector is developed. Detection efficiency is determined by employing Monte Carlo method. Experimental results are described, and they show the workability of the method. (20 refs.)

78701 Seismic velocity anisotropy in a medium containing oriented cracks—transversely isotropic case. O.Nishizawa (Geological Survey of Japan, Ibaraki, Japan).

J. Phys. Earth (Japan), vol.30, no.4, p.331-47 (1982).

A new method is developed for calculating effective elastic parameters of a medium containing oblate spheroidal cracks having parallel planes. This new method is free from the restrictions of isotropic matrix material and low crack density. Velocity anisotropy is calculated for the case of oriented cracks filled with fluid. Effects of crack aspect ratio, fluid bulk modulus, and crack volume on velocity anisotropy are investigated. The present results show smaller anisotropy than that given by Anderson et al. (1974) for a medium containing oriented spheroidal cracks. The relation between velocity and crack density parameter using these results. (25 refs.)

78702 Development trends in hygrometry. M.A.Berliner.

Meas. Tech. (USA), vol.25, no.9, p.754-8 (Sept. 1982). Translation of: *Izmer. Tekh. (USSR)*, vol.25, no.9, p.44-6 (Sept. 1982). [received: May 1983]

Advances in hygrometry methods and facilities are discussed, particular attention being paid to the influence of microcircuit technology. Advances in processing and displaying data are also discussed and the role of microprocessors is emphasised. A method of choosing the optimal design of a hygrometer with regard to metrological characteristics, working characteristics, economic parameters, ergonomics and metrological support is presented. (7 refs.)

78703 Development prospects for dewpoint hygrometers. V.P.Petukhov.

Meas. Tech. (USA), vol.25, no.10, p.847-50 (Oct. 1982). Translation of: *Izmer. Tekh. (USSR)*, vol.25, no.10, p.46-8 (Oct. 1982).

Discusses the general trends in the development of dewpoint hygrometers. These include implementation of microelectronic and microprocessor devices which provide a basis for control systems for measuring the humidity over a wide dewpoint range. Such systems can provide stabilisation of the condensate film and can include self-monitoring and fault-diagnosis systems. The general structure of an automatic flow hygrometer with a wide dewpoint range is described. (13 refs.)

78704 Field differential hygrometer. V.A.Glushikin, S.I.Krechmer.

Meas. Tech. (USA), vol.25, no.10, p.850-2 (Oct. 1982). Translation of: *Izmer. Tekh. (USSR)*, vol.25, no.10, p.48-50 (Oct. 1982).

Discusses the development of a field meter for the humidity profile, which in essence consists of two identical dewpoint hygrometers. The measuring systems can measure and record the absolute humidity (dewpoint temperature) and the difference in humidity at two points of measurement simultaneously. The hygrometer consists of two blocks: a stationary one and a head unit, which are connected by a cable. In gradient measurements with two hygrometers, the thermocouples enable one to duplicate the dewpoint-difference measurements and to measure the difference in air temperature. Field measurement conditions differ from laboratory ones mainly in three factors: it is necessary to place the transducer at a large distance from the stationary unit, there is a wind that alters the temperature equilibrium in a random fashion, and the solar radiation affects the automatic-control system. (1 ref.)

78705 Ultraviolet hygrometer for measuring fluctuations in α atmospheric humidity. S.I.Kreshmer, S.A.Sitnov, V.V.Kudryavtsev.

Meas. Tech. (USA), vol.25, no.10, p.859-62 (Oct. 1982). Translation of: *Izmer. Tekh. (USSR)*, vol.25, no.10, p.56-8 (Oct. 1982).

Advantages of a UV hygrometer, particularly for field measurements, are that the mass and size are comparatively small, the baseline is short (only 15-20 mm), and the design is simple. Operation of the UV hygrometer is described and its development in the Soviet Union is discussed. An advanced version of the UV hygrometer is described which operates in the range 103 to 4×10^3 Pa with an overall error 6Pa is described. Examples of fluctuation curves obtained with this hygrometer on the Black Sea expedition are presented. (16 refs.)

78706 Estimation of source function and medium response function by autoregressive method. G.J.Nair (Bhabha Atomic Res. Centre, Bombay, India).

Phys. Earth & Planet. Inter. (Netherlands), vol.32, no.1, p.36-44 (April 1983).

By modelling seismograms as 'low' and 'high' order autoregressive (AR) processes, the source function and the medium response function are separated from a single channel seismogram. Akaike's final prediction error is used to select the appropriate 'low' and 'high' AR order of the process. Case studies of synthetic data show that the recovered source and reflectivity functions compare very well with the input functions. Using this method, arrivals of the surface reflected P phases of five explosions from the Soviet region and of two earthquakes from Kamchatka, recorded at Gauribidanur, India, are identified. Certain features of the source and source region of these events are also inferred. (15 refs.)

78707 Acoustic remote sensing of the boundary layer. S.P.Singal, B.S.Gera (Nat. Phys. Lab., New Delhi, India).

Proc. Indian Acad. Sci. Eng. Sci., vol.5, pt.2, p.131-57 (July 1982). [received: April 1983]

An acoustic echo sounder (called sodar) has been developed, designed and fabricated. This equipment has been operating successfully for several years and has been shown to have important applications in the areas of air pollution control, studies, microwave and millimetre wave radio communication including troposcatter, aviation and micrometeorology. Work on the development of the sodar was taken up at the Indian National Physical Laboratory (NPL) in 1972. At that time, this was one of the few equipment of its kind in the world. It has been designed in the laboratory and has been built with indigenous components. The equipment currently probes the thermal structure of the atmosphere upto a height of 700 m but can be extended to a kilometre. Two sodars are in operation—one at the National Physical Laboratory, Delhi and the other at the Micrometeorological Laboratory, Tarapur in collaboration with BARC, Bombay. The design criteria of the NPL sodar and experiments with it are described in this paper. (36 refs.)

78708 Airflow resistivity instrument for in situ measurement on the Earth's ground surface. A.J.Zuckerwar (NASA-Langley Res. Center, Hampton, VA, USA).

Rev. Sci. Instrum. (USA), vol.54, no.5, p.597-9 (May 1983).

An airflow resistivity instrument features a novel specimen holder, especially designed for in situ measurement on the Earth's ground surface. This capability eliminates the disadvantages of prior intrusive instruments, which necessitate the removal of a test specimen from the ground. A prototype instrument can measure airflow resistivities in the range 10-5000 cgs rayl/cm, at specimen depths up to 15.24 cm (6 in.), and at differential pressures up to 2490.8 dyn/cm² (1 in. H₂O) across the specimen. Because of the close relationship between flow resistivity and acoustic impedance, this instrument should prove useful in acoustical studies of the Earth's ground surface. Results of airflow resistivity measurements on an uncultivated grass field for varying values of moisture content are presented. (6 refs.)

78709 Estimation of f_oF_2 from interferences appearing on AGC data of ISS-b topside sounder. S.Igi, N.Matsumura.

Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.333-43 (June 1982). In Japanese.

Concerns a method for estimation of f_oF_2 from the lowest frequency of the interferences appearing on automatic gain control (AGC) data of the topside sounder on-board ISS-b. For frequencies below f_oF_2 , the AGC output is mainly caused by the background noises from cosmic origin revealing a monotonous frequency distribution, while for frequencies above f_oF_2 , the AGC output is mainly caused by the interferences from the ground radio origin exhibiting rather complex frequency structures with high intensity levels. Such a change in the frequency distribution of the sounder AGC data provides a possibility for estimation of f_oF_2 values by detecting the lowest frequency of the interferences, f_i . In order to investigate validity of the method for f_oF_2 estimation, a statistical comparison was made with respect to about 47000 ionograms from ISS-b between the f_oF_2 values scaled from the echo traces on the topside ionograms and the f_i values determined from the sounder AGC data with the aid of computer processing. The results show that the value of f_i provides a fairly accurate estimation of f_oF_2 value over the regions where the intensity of man-made noises is high, while the accuracy is influenced by the D-region absorption of the ground noises during daytime and by existence of the ionospheric irregularities. (7 refs.)

78710 Measurement of total electron content by simultaneous reception of ISS-b telemetry signals. K.Aikyo, T.Marukaya, M.Kotaki.

Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.479-89 (June 1982). In Japanese.

The ISS-b carries two telemetry transmitters with frequencies in VHF (136.810 Hz) and UHF (400.900 MHz) bands. Both telemetry signals are PCM-modulated by the identical data with a bit rate of 26.624 kbps for the dump-mode and 1.024 kbps for the realtime-mode. The measurement of the differential time-delay between two signals by time comparison of the decoded waveforms enables measurement of the total electron content (TEC) of the ionosphere along the ray path between the spacecraft and the ground station. The authors deal with the principle, the measuring implement, evaluation of the errors in the measured time delay and the method of calibration. A comparison is also made between the TEC measured above Kashima and the first order mid-latitude TEC model derived by Klobuchar and Allen (1970). Consequently, it is confirmed that this method gives columnar TEC data in good accuracy even for oblique propagation except in case of the large horizontal gradient in electron density. (20 refs.)

78711 Radial characteristics of focusing probes of magnetoelectric logging. L.A.Taborovskii, Yu.A.Dashevskii (Inst. of Geology & Geophys., Acad. of Sci., Novosibirsk, USSR).

Sov. Geol. & Geophys. (USA), vol.23, no.3, p.71-9 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.3, p.81-90 (1982).

Continues studying the geophysical possibilities of the method of magnetoelectric logging (MEL) of boreholes. A method is proposed for geometric focusing at a constant current, which permits elimination of the influence of the borehole and the penetration zone from the measurement results. The parameters of the MEL focusing systems are calculated, and their radial characteristics studied. The authors investigate the problems which have a direction relationship to the technical implementation of the method: influence of the insulating base of the probe and calibration of the equipment which records the magnetic field. (2 refs.)

78712 Use of residual gravity anomalies to estimate the scale of ore fields. V.I.Andreev, M.G.Stuskin (Inst. of Mineral Resources, Dnepropetrovsk, USSR).

Sov. Geol. & Geophys. (USA), vol.23, no.3, p.96-8 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.3, p.108-10 (1982).

Proposes a new noise-resistant method of determining anomalous mass (ore reserves) and dimensions of isolated or compactly grouped sources, whose shape is close to isometric. The method is integral with respect to content; the authors use a transformant which is calculated as the ratio of the difference in the values of gravity, averaged for the vicinities of two radii, to the difference of these radii, which does not depend on the regional (constant and linear) constituents. The authors use sources of the gravity field situated in a certain depth interval. (4 refs.)

78713 A method of studying the Earth's crust by refracted P- and S-waves. A.L.Aleynikov, S.N.Golod, A.M.Tuinova (Inst. of Geophys., Sverdlovsk, USSR).

Sov. Geol. & Geophys. (USA), vol.23, no.3, p.109-15 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.3, p.120-7 (1982).

A method is proposed for reproducing the velocity cross section by travel-time curves of first waves with a random law of variation of velocity with depth (even in the presence of a waveguide). The method finds application in engineering seismics, seismic exploration, and deep seismic sounding. Its use for interpretation of P- and S-waves permitted the development of a method to estimate the density and composition of deep rocks with considerably greater reliability than before. (21 refs.)

78714 Approximate analogs of Dix formulas for a stratified medium with curvilinear boundaries and variable bed velocities. E.A.Biyas (Inst. of Geology & Dev. of Mineral Fuels, Acad. of Sci., Kuibyshev, USSR).

Sov. Geol. & Geophys. (USA), vol.23, no.3, p.116-22 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.3, p.128-35 (1982).

A method is proposed for approximate solution of the kinematic problem for a stratified medium with curvilinear boundaries and variable bed velocities, based on the approximate reverse of the formulae obtained previously for solving the direct problem. (3 refs.)

78715 On the theory of the three-element probe in electromagnetic wave logging. Yu.N.Antonov, V.G.Burkov (Inst. of Geology & Geophys., Novosibirsk, USSR).

Sov. Geol. & Geophys. (USA), vol.23, no.4, p.50-7 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.4, p.58-65 (1982).

The relative characteristics of electromagnetic wave logging (EMWL) are classified according to the sensitivity to dielectric permeability and the specific electrical resistivity of the rocks. The authors describe a synthesis of the original characteristics of the field, whose measurement makes it possible to determine the dielectric permeability of high- and low-resistivity, oil-, gas-, and water-bearing strata. (12 refs.)

78716 The determination of stratal velocities in horizontally layered media by the hyperboloid approximation of hodographs. E.A.Blyas.

Sov. Geol. & Geophys. (USA), vol.23, no.4, p.58-64 (1982). Translation of: *Geol. & Geofiz. (USSR)*, vol.23, no.4, p.66-71 (1982).

The new method of determining the strata velocities in horizontally layered media proposed does not require finding the limiting effective parameters (the first two terms in the expansion of the reflected-wave hodographs), but uses the parameters of hyperbolas approximating real hodographs. An example illustrating the effectiveness of the method is given. (6 refs.)

78717 High resolution spectral analysis and the acoustic remote sensing of ocean current velocity. W.S.Hodgkiss, D.S.Hansen (Marine Phys. Lab., Scripps Inst. of Oceanography, San Diego, CA, USA).

Proceedings of ICASSP 83. IEEE International Conference on Acoustics, Speech and Signal Processing, Boston, MA, USA, 14-16 April 1983 (New York, USA: IEEE 1983), p.961-4 vol.3.

Doppler sonars use the perceived shift in carrier frequency between the outgoing pulse and returning echo to estimate scatterer radial velocity at several ranges of interest. Scatterers suspended neutrally buoyant in the water column are used as tracers for the remote sensing of water mass motion. The application of pth-order autoregressive time series analysis models to estimation of the time-evolving Doppler sonar reverberation power spectrum is reported. With the aid of a reverberation model, it is shown that the spatial transfer function characteristics of a transducer have a significant influence on the time-evolving shape of the reverberation power spectrum. Thus, it is suggested that the use of first-order models for the purpose of Doppler shift estimation simply is inadequate. The results of an exploratory analysis of pings from a 67 kHz Doppler sonar appear to confirm this caution. (11 refs.)

78718 Lower bounds on pulsed-Doppler current profiler accuracy. K.B.Theriault (Bolt Beranek & Newman Inc., Cambridge, MA, USA).

Proceedings of ICASSP 83. IEEE International Conference on Acoustics, Speech and Signal Processing, Boston, MA, USA, 14-16 April 1983 (New York, USA: IEEE 1983), p.985-8 vol.3.

Lower bounds on performance (velocity and shear estimate variance) are computed for a four-beam pulsed Doppler shear profiler system. It is shown that performance is asymptotic to a constant as SNR increases; this is evidently due to the assumed incoherent scattering properties of the medium. Curves and expressions are presented which define the tradeoffs between resolution and accuracy for an operational system. (6 refs.)

78719 Primitive extraction for a syntactic pattern recognizer of features in seismic signals. J.E.Gaby (Engng. Experiment Station, Georgia Inst. of Technol., Atlanta, GA, USA), K.R.Anderson.

Proceedings of ICASSP 83. IEEE International Conference on Acoustics, Speech and Signal Processing, Boston, MA, USA, 14-16 April 1983 (New York, USA: IEEE 1983), p.993-6 vol.3.

Describes research into the morphological structure of regional seismic signals. This study is designed to aid in the development of a syntactic pattern recognition system to automate the analysis of seismic signals. (4 refs.)

78720 The wavelet reconstructed with phase-only and a study of its uniqueness. Tong Chang, Yenta Li, Zhongze Wu (Dept. of Automation, Qinghua Univ., Beijing, China).

Proceedings of ICASSP 83. IEEE International Conference on Acoustics, Speech and Signal Processing, Boston, MA, USA, 14-16 April 1983 (New York, USA: IEEE 1983), p.997-1000 vol.3.

The concept of waveform uniqueness in deconvolution of seismic traces is discussed. Under this conception, mixed-phase wavelets can be classified into three types. Based on the theorem of uniqueness of a sequence with a phase function by M.H. Hayes et al. (1981) and with some extensions, two types of wavelets have been reconstructed using a zero-perturbation relaxed iterative algorithm. A new criterion function which judges the convergence of iteration and a new criterion of classification are also presented. Several examples of mixed-phase wavelet reconstruction are provided. (3 refs.)

78721 Seismic velocity estimators. R.L.Kirlin, L.A.Dewey (Electrical Engng. Dept., Laramie, WY, USA).

Proceedings of ICASSP 83. IEEE International Conference on Acoustics, Speech and Signal Processing, Boston, MA, USA, 14-16 April 1983 (New York, USA: IEEE 1983), p.1001-4 vol.3.

The layered subsurface geologic model leads to an approximate hyperbolic curve of delay vs. sensor offset distance for seismic signals. Four 'optimum' estimators for the RMS seismic velocity are given and analyzed by simulation for RMS error. Parameters varied include center-point depth (time), a priori velocity variance and mean, delay-estimate variance and inter-delay-estimate correlation. The maximum likelihood estimator is shown to be best when a priori information is relatively good, but a least mean square estimator is best otherwise. (4 refs.)

78722 Deconvolution of band-limited signals. D.R.Martinez, S.H.Bickel (ARCO Oil & Gas Co., Dallas, TX, USA).

Proceedings of ICASSP 83. IEEE International Conference on Acoustics, Speech and Signal Processing, Boston, MA, USA, 14-16 April 1983 (New York, USA: IEEE 1983), p.1009-12 vol.3.

The inverse filter to a minimum-phase wavelet with infinite bandwidth is often calculated from its autocorrelation by applying the Wiener-Levinson algorithm. Physical limitations of seismic data require the wavelet to have a finite bandwidth which violates the minimum-phase condition. An unstable filter results when the Wiener-Levinson algorithm is applied to band-limited data. Although 'processing noise' is often added to stabilize the algorithm, this procedure can obscure problems associated with the data instability from the seismic interpreter. This paper presents an approach to the deconvolution of band-limited data by mapping the frequency response to span the full spectrum based on a set of sampling rate changes according to the lower and upper frequency cutoffs. (6 refs.)

78723 A model reduction algorithm by spline approximation in the deconvolution of seismic signals. S.D.Kollias, C.C.Halkias (Dept. of Electronics, Nat. Tech. Univ. of Athens, Athens, Greece).

Proceedings of ICASSP 83. IEEE International Conference on Acoustics, Speech and Signal Processing, Boston, MA, USA, 14-16 April 1983 (New York, USA: IEEE 1983), p.1013-16 vol.3.

A new method for obtaining approximate low-order recursive (ARMA) realizations of convolution models is based upon optimum piecewise linear or cubic spline approximation of the convolution kernel. The basic seismic wavelet is approximated by splines and a fixed-lag smoothing state-space representation, equivalent to the resulting ARMA model, is derived. Use of Kalman filtering gives fixed-lag smoothed estimates of the so-called reflection coefficient sequence. Adaptive estimation is used when the seismic wavelet is not known a priori. Simulation results using a Ricker wavelet illustrate the performance of the proposed method. (10 refs.)

78724 EISCAT—the facility, the technique, and representative early results. M.J.Baron, K.Folkestad.

Third International Conference on Antennas and Propagation ICAP 83, Norwich, England, 12-15 April 1983 (London, England: IEE 1983), p.169-75 part 2.

The EISCAT Scientific Association was created as an educational and scientific organization to conduct high latitude upper atmosphere research, using the incoherent scatter radar technique. For this purpose, two high-power radar systems were designed for installation and operation in northern Scandinavia. The tri-static UHF system began operations in the summer of 1981. The monostatic VHF is scheduled for completion in 1983. This paper first reviews the incoherent scatter technique. Then, the EISCAT facility itself is described. Finally, some representative results are shown. (9 refs.)

78725 An incoherent scatter study of short- and long-term temperature and atomic oxygen variations in the thermosphere. J.Fontanari (CESR, Univ. Paul Sabatier, Toulouse, France), D.Alcayde, P.Bauer. *Ann. Geophys. (France)*, vol.1, no.1, p.81-9 (Jan.-Feb. 1983). Diurnal distributions of exospheric temperature and atomic oxygen concentration at 200 km, deduced from incoherent scatter observations during the period 1974-1977, are fitted by a function including a mean value and diurnal and semi-diurnal oscillations. The characteristics of each component are combined with similar values obtained in the same way during high solar activity (1969-1972). All the data are then analyzed in order to evidence long-term variations (seasonal, annual, and as a function of geomagnetic activity indices), over a large range of solar activity (70 to 170×10^{22} Jansky). The results of the analysis of the diurnal temperature profiles from 120 to 200 km are compared to those obtained from independent data gathered in the upper thermosphere. (25 refs.)

78726 The diurnal and semidiurnal oscillations in meteor winds over Atlanta. M.I.Ahmed, R.G.Roper (School of Geophys. Sci., Georgia Inst. of Technol., Atlanta, GA, USA).

J. Atmos. & Terr. Phys. (GB), vol.45, no.4, p.181-92 (April 1983).

The wind data collected over Atlanta during the period August 1974-February 1978 using the Georgia Tech. Radio Meteor Wind Facility, is analyzed to yield an average picture of the seasonal behavior of its diurnal tides. Both the zonal and meridional components are studied. The vertical structures of these oscillations over Atlanta are compared with similar studies over Garchy, Urbana and Adelaide. (16 refs.)

78727 The dissipation of a sodium cloud. V.W.J.H.Kirchhoff, B.R.Clemesha (INPE Conselho Nacional de Desenvolvimento Científico e Tecnológico, Sao Paulo, Brazil).

Planet. & Space Sci. (GB), vol.31, no.4, p.369-72 (April 1983).

Occasional observations of strong increases in the atmospheric sodium densities and/or Na nightglow intensities suggest that the cause is the deposition of a sodium cloud in addition to the local equilibrium sodium layer. This situation is simulated to investigate the response of the atmospheric sodium layer to variations of the source influx rate. The settlement of the sodium to the equilibrium layer after the deposition of a sodium cloud is shown to be a long lived event in which the excess sodium is transported downwards, to the sink, by eddy diffusion. The possibility of a modulated source influx rate is also investigated showing a tendency for a strong attenuation of this modulation below the source. (15 refs.)

78728 Night intensity of oxygen triplet about $\lambda 1304 \text{ \AA}$ in upper atmosphere. K.B.Serafimov (Central Lab. for Space Res., Bulgarian Acad. of Sci., Sofia, Bulgaria).

C.R. Acad. Bulg. Sci. (Bulgaria), vol.36, no.3, p.337-40 (1983). (13 refs.)

78729 Measurements of the structure and drift velocities of airglow ($\lambda=557.7$ nm) irregularities: Saskatoon (52°N , 107°W), Canada. C.E.Meek, A.H.Manson (Inst. of Space & Atmospheric Studies, Univ. of Saskatchewan, Saskatoon, Canada).

J. Atmos. & Terr. Phys. (GB), vol.45, no.4, p.203-12 (April 1983).

A scanning photometer is used in conjunction with moving pattern analysis, to measure the horizontal motion of fluctuations in the airglow (557.7 nm) intensity: a modified full correlation analysis, and spatial correlation function analysis are used. The directions of these drifts often differ by $\geq 90^\circ$ from winds measured simultaneously by a medium frequency radar system. Temporal fluctuations of the airglow intensity, and the spectra of these, are interpreted in terms of internal gravity waves ($\sim 10 > \tau > 90$ min) and the semi-diurnal tide. (28 refs.)

78730 Intensity variations and ratios of (9-4) and (7-3) hydroxyl bands in nightglow at Poona. S.R.Gogawale, A.D.Tillu (Dept. of Phys., Poona Univ., Pune, India).

Planet. & Space Sci. (GB), vol.31, no.4, p.423-33 (April 1983).

The observed types of nocturnal intensity variations for the OH (9-4) and OH (7-3) bands during IQSY at this station, are further analysed using the theoretical band intensity distribution of Evans and Llewellyn (1972). A considerable agreement is noticed between observed and theoretical intensity ratios, $I(9-4)/I(7-3)$, for a major portion of the data ($\sim 70\%$) which has a 'continuous decrease' type of nocturnal intensity variation. For the remaining portion of the data ($\sim 30\%$), which has an 'increase followed by decrease' type of intensity variation and higher intensities, the observed ratios are also systematically higher than the above. A satisfactory explanation is offered, by postulating a second layer of emission. (60 refs.)

94.10S Aurora

78731 Radar auroral observations and ionospheric electric fields. E.Nielsen (Max-Planck-Inst. für Aeronomie, Katlenburg-Lindau, Germany), J.D.Whitehead.

Adv. Space Res. (GB), vol.2, no.7, p.131-44 (1982).

The ground-based systems STARE and SABRE utilize radar auroral phenomena to estimate ionospheric electric fields. Some of the assumptions

underlying these systems have been tested and general agreement with expectations have been found. However, as the results have been analysed in detail, it has become clear that the error in the irregularity drift velocity can at times amount to 100 ms^{-1} . Direct comparisons with other E-field measurements, as well as assessments of the results of applications of the STARE data clearly demonstrate that the electric field, calculated on the basis of the irregularity drift velocity, is a useful estimate of the actual horizontal electric field in the ionosphere and is sufficiently accurate for a great variety of geophysical studies. (34 refs.)

94.20 PHYSICS OF THE IONOSPHERE

(for planets, see 96.30)

78732 Radio aurora magnetic and streaming aspect sensitivities on 6 simultaneous links at 50 MHz. G.J.Sofko (Inst. of Space & Atmospheric Studies, Univ. of Saskatchewan, Saskatoon, Saskatchewan, Canada), J.A.Koehler, J.Gilmer, A.G.McNamara, D.R.McDiarmid.

Adv. Space Res. (GB), vol.2, no.7, p.149-52 (1982).

During August 1981, a 50 MHz c.w. radar system was operated in central Canada to measure auroral scatter amplitudes and Doppler spectra from a scattering region centered near 66° magnetic invariant latitude ($L \approx 6.0$). Narrow beams from 3 transmitters, differing in frequency by 1 KHz, were directed to cover a common volume of the ionosphere over a ground location at 56.3°N , 103.5°W . The scattered signals were received on narrow beam antennas at two receiving sites, and recorded in analog form on magnetic tape under the control of an AIM65 microcomputer. The analog tapes were digitized later and FFT-processed to obtain Doppler spectra and amplitudes. Preliminary results are reported. (9 refs.)

78733 Some modifications of Jaeger's formula [ionospheric absorption]. R.Misra (Contai P.K. Coll., Midnapur, West Bengal, India), B.Chakravarty.

Indian J. Theor. Phys., vol.29, no.3, p.261-9 (Sept. 1981).

The drawbacks in the application of Jaeger's formula to absorption calculations have been discussed. Some modified forms of this formula have been presented which are suitable for application under various conditions. The values of absorption have been calculated with the modified form of Jaeger's formula taking ν and f_i into consideration. It has been shown that the values of absorption calculated with Jaeger's formula on replacing f_o/f by F_o/F agree with those from magneto-ionic theory. (13 refs.)

78734 Simple M-factor algorithm for improved estimation of the basic maximum usable frequency of radio waves reflected from the ionospheric F-region. M.Lockwood (Rutherford Appleton Lab., Chilton, Didcot, England).

IEE Proc. F (GB), vol.130, no.4, p.296-302 (June 1983).

The equations of Milsom are evaluated, giving the ground range and group delay of radio waves propagated via the horizontally stratified model ionosphere proposed by Bradley and Dudeney. Expressions for the ground range which allow for the effects of the underlying E- and F1-regions are used to evaluate the basic maximum usable frequency or M-factors for single F-layer hops. An algorithm for the rapid calculation of the M-factor at a given range is developed, and shown to be accurate to within 5%. The results reveal that the M(3000)F2-factor scaled from vertical-incidence ionograms using the standard URSI procedure can be up to 7.5% in error. A simple addition to the algorithm effects a correction to ionogram values to make these accurate to 0.5%. (14 refs.)

78735 Autumn and winter anomalies in ionospheric absorption as measured by riometers. H.Ranta, A.Ranta, T.J.Rosenberg, D.L.Detrick (Inst. for Phys. Sci. & Technol., Univ. of Maryland, College Park, MD, USA).

J. Atmos. & Terr. Phys. (GB), vol.45, no.4, p.193-202 (April 1983).

Seasonal variation of ionospheric absorption has been studied on the basis of riometer (A2) measurements obtained over a wide latitude range. Equinoctial maxima of approximately equal amplitude are observed in the auroral zone and near the equator. At mid-latitudes riometer absorption maximizes during the fall. The autumn maximum or autumn anomaly, in riometer absorption is observed at much higher geographic latitude in the southern than in the northern hemisphere but at comparable geomagnetic latitudes in both hemispheres. The different methods to determine a quiet-day curve are discussed. (23 refs.)

78736 Refractive index surfaces. G.F.Stott (Cavendish Lab., Univ. of Cambridge, Cambridge, England).

J. Atmos. & Terr. Phys. (GB), vol.45, no.4, p.219-29 (April 1983).

The refractive index surface is a very powerful concept which has been widely used for describing electromagnetic wave propagation in the plasmas of the Earth's ionosphere and magnetosphere. Because of the simple analytic form of the cold plasma dispersion relation it is possible to examine in some detail the properties of these refractive index surfaces. The purpose of this paper is to review briefly the properties that are widely known and present some features which have not been previously discussed. (25 refs.)

78737 Loss cone fluxes and pitch angle diffusion at the equatorial plane during auroral radio absorption events. P.N.Collis, J.K.Hargreaves (Dept. of Environmental Sci., Univ. of Lancaster, Lancaster, England), A.Korth.

J. Atmos. & Terr. Phys. (GB), vol.45, no.4, p.231-43 (April 1983).

The flux and pitch angle distribution of energetic electrons near the loss cone have been investigated over the energy range 15-300 keV, using measurements on the geosynchronous satellite GEOS-2 at the times of auroral radio absorption events detected by riometers in Scandinavia. It is shown that conditions of strong pitch angle diffusion apply only during the most intense absorption events ($\geq 6 \text{ dB}$ at 30 MHz) which are relatively infrequent. During most events the loss cone is partially depleted, with the degree of depletion increasing as the absorption becomes weaker. The variation of the pitch angle diffusion coefficient with the observed radio absorption is estimated. An empirical law is derived which enables the computation of radio absorption consistent with measurements. D-region recombination laws are discussed and limits are set on the height profile of the effective recombination coefficient. (41 refs.)

78738 Lunar modulation of the equatorial electrojet. K.Maeda.

J. Atmos. & Terr. Phys. (GB), vol.45, no.4, p.245-54 (April 1983).

An attempt has been made to reproduce the counter electrojet (CE) in the equatorial dynamo by considering neutral winds with solar (1-2), (2,4), (2,2) and lunar (2,2) tidal modes as well as a constant electrostatic field (E_e). The daily variation of conductivity (σ) is assumed to consist of steady (average), diurnal and semi-diurnal components. An equation governing the relationship between j_y (jet current), E_e , σ and wind is given, and this equation is then used to describe diurnal, semi-and ter-diurnal variations of j_y separately. The

seasonal characteristics and the solar activity dependence of CE are demonstrated to be predictable. (33 refs.)

78739 Travelling ionospheric disturbances detected by UHF angle-of-arrival measurements. J.V.Evans (MIT Lincoln Lab., Lexington, MA, USA), R.H.Wand.

J. Atmos. & Terr. Phys. (GB), vol.45, no.4, p.255-65 (April 1983).

From January 1971 to March 1973, the Millstone Hill L-band satellite tracking radar was employed in a study of ionospheric refraction. Satellites of the Navy Navigation Series were tracked smoothly by radar (at 1295 MHz) by commanding the 84-ft diameter antenna to follow the predicted path of the satellite across the sky, and allowing any measured angular errors slowly to close out the offsets. Simultaneously, the apparent position of the satellite was sensed passively by receiving (on the same antenna) the UHF beacon signals. Ionospheric refraction manifested itself during the rising and setting portions of the path as a displacement between the UHF and L-band apparent positions. In addition, quasi-sinusoidal fluctuations in the displacement were seen at intervals along the path that are believed to be caused by travelling ionospheric disturbances. These TIDs appear to be confined largely to the lower thermosphere and manifest themselves in tilting the lower surface of the ionosphere where the density gradients are largest. (41 refs.)

78740 Collision frequencies in the high-latitude D-region. M.Friedrich (Dept. of Communications & Wave Propagation, Tech. Univ. Graz, Graz, Austria), K.M.Torkar.

J. Atmos. & Terr. Phys. (GB), vol.45, no.4, p.267-71 (April 1983).

D-region collision frequencies derived from rocket flights are subjected to a harmonic seasonal analysis. The proportionality between collision frequency and pressure has been derived and found to be in excellent agreement with laboratory data. Some implications of the results are discussed. (15 refs.)

78741 The effects of neutral air winds on the electron content of the mid-latitude ionosphere and protonosphere in summer. G.C.Sethia (Dept. of Environmental Sci., Univ. of Lancaster, Lancaster, England), G.J.Bailey, R.J.Moffett, J.K.Hargreaves.

Planet. & Space Sci. (GB), vol.31, no.4, p.377-87 (April 1983).

The effects of neutral air winds on the electron content and other parameters of the mid-latitude ionosphere are modelled by means of mathematical solutions of the time-dependent continuity and momentum equations for oxygen and hydrogen ions. The geometry is chosen to represent a propagation path between a geosynchronous satellite and a ground station, and the computations are compared with results from slant path observations of the ATS-6 radio beacon made at Lancaster (UK) and Boulder, Colorado (USA). (15 refs.)

78742 Plasmaspheric hiss observed in the topside ionosphere at mid-and low-latitudes. T.Ondoh, Y.Nakamura, S.Watanabe, K.Aikey, T.Murakami (Radio Res. Labs., Tokyo, Japan).

Planet. & Space Sci. (GB), vol.31, no.4, p.411-22 (April 1983).

Latitudinal characteristics of ELF hiss in mid- and low-latitudes are statistically studied by using ELF/VLF electric field spectra (50 Hz-30 kHz) from ISIS-1 and -2 received at Kashima station, Japan, from 1973 to 1977. The ELF hiss is classified into the steady ELF hiss whose upper frequency limit is approximately constant with latitude and the ELF hiss whose upper frequency limit increases with latitude. Spectral shape and bandwidth of ELF hiss in the topside ionosphere and the occurrence rate are discussed. ELF hiss events correlation with geomagnetic activity are discussed. Ray tracing results suggest that waves of ELF hiss generated in the equatorial outer plasmasphere propagate down in the electrostatic whistler mode towards the equatorial ionosphere, bouncing between the LHR reflection points in both the plasmaspheric hemispheres. (16 refs.)

78743 Global distribution of the ionospheric F-layer critical frequency f_oF_2 . N.Matuura, K.Aikey, R.Nishizaki, T.Ogata, S.Igi, T.Maryuma, H.Yabuuma, M.Yamanishi, T.Ide.

Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.315-31 (June 1982). In Japanese.

The critical frequency of the ionospheric F-layer f_oF_2 , one of the basic parameters of the ionosphere, was derived from the topside sounding data obtained by the digital type swept-frequency sounder on-board the ISS-b. The measurements of f_oF_2 were carried out on a routine basis with three or four observational revolutions operated in a day, where the values of f_oF_2 at about 100 data points were obtained from each revolution. Global mapping analysis was performed with respect to each data group of the world-wide f_oF_2 data collected from those observed within each four-months period between August 1978 and June 1979 and also within the time interval of ± 1 hr around each hour of UT. The mapping analysis was carried out in the manner as determining the coefficients of the functional form of the spherical surface harmonic expansion to make it best fit to the global data of the observed f_oF_2 . The authors describe the global observation by ISS-b, the global mapping analysis of f_oF_2 , the comparison of the results with those from ground based observations including the CCIR model, and some characteristics of the global distribution of f_oF_2 . (13 refs.)

78744 Global distribution of topside spread F. T.Maryuma, N.Matuura.

Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.345-55 (June 1982). In Japanese.

The global distribution of the occurrence probability of topside spread F is investigated through the analysis of topside ionograms recorded by the ISS-b satellite for the period from April 1978 to June 1980. The latitudinal distribution of the spread F shows two distinct high occurrence regions, mid to higher latitudes and equatorial latitudes, with relatively low occurrence regions at around 30° in magnetic latitude between the two in both the northern and southern hemispheres. Spread F at the equatorial latitudes (ESF), which is a night-time phenomenon, exhibits clear longitudinal-seasonal variation in the occurrence; for the northern winter and for the northern summer seasons high occurrence of ESF observed at the Atlantic longitudes and at the Pacific longitudes, respectively. Spread F at mid to higher latitudes appears throughout all the local time, and the occurrence probability of that increases with latitudes. Longitudinal dependence of the spread F occurrence in the night-time is also found at mid latitudes in the winter hemisphere. (25 refs.)

78745 Long-distance HF propagation modes deduced from the simultaneous observation by chirp sounder and ISS-b. M.Ichinose, S.Fujii, K.Nozaki, S.Igi.

Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.357-63 (June 1982). In Japanese.

The propagation modes on 9200 km circuit from Federal Republic of Germany to Japan were identified based on the chirp oblique sounding data and also the ionospheric data along the circuit which were obtained by Ionosphere Sounding Satellite-b (ISS-b). The oblique sounding ionograms for the circuit were obtained every hour during the period from November 1978 to May 1979 by the chirp-sounder operated with the swept frequency range from 4 to 30 MHz. The ionospheric condition along the circuit was observed by ISS-b of which orbital path could be fairly close to the circuit on some

occasions. The propagation time on the circuit were calculated for every frequency steps by substituting the ionospheric factor of the control points to the analytical formulas which were introduced for the parabolic model of the F2 layer. The traces for the oblique ionogram were simulated by plotting these calculated propagation time against the frequency. The simulated traces for 3- to 5-hop propagation modes were compared with those obtained from observations. The results show that the MOF is greater than the theoretical MUF by about 1 MHz. (7 refs.)

78746 Short-term prediction of HF propagation. Y.Takenoshita, S.Ito, R.Maeda, T.Koizumi.

Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.365-7 (June 1982). In Japanese.

Global maps of the MUF variability were made from the F-layer critical frequencies observed with the Ionosphere Sounding Satellite-b from October 1978 to March 1979. The maps were used weekly in a trial to correct the monthly MUF of HF circuits predicted in advance of three months by the Radio Research Laboratories. The correction was carried out as a weekly prediction with consideration of temporal and spatial characteristics found in the CCIR MUF maps. An adequacy of the trial was examined, taking into account of HF circuit data obtained at Hiraio Branch. The trial with the most reliable data succeeded 55 times, failed 6 times and missed 39 times in correction. (no refs.)

78747 The effects of the ionosphere on the extent of the radio horizon at high frequency band. M.Kotaki, I.Kuriki, C.Kato, H.Suguchi.

Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.399-409 (June 1982). In Japanese.

In order to estimate the size of the radio window viewed from the satellite with high frequency radio waves, the computational study of three dimensional ray trajectories in anisotropic and inhomogeneous ionospheres has been made. The size of the radio window changes with frequency of emitted radio waves and the properties of the ionosphere such as the electron density, the thickness and gradient of the layer. The authors clarify the relations between the size of the radio window and the characteristics of the ionized media. The calculated results are supported experimentally by observations of the Ionosphere Sounding Satellite (ISS-b). (2 refs.)

78748 Observations of the thermal plasma in the topside ionosphere by RPT mission of ISS-b: electron density, temperature and mean ion mass. E.Sagawa, S.Miyazaki, H.Mori, T.Ogawa.

Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.435-47 (June 1982). In Japanese.

Procedures and results of analysis of the electron data (Langmuir curves) obtained by RPT mission of ISS-b are presented. The electron density (N_e), electron temperature (T_e), and mean ion mass (M_i) are deduced from a Langmuir curve of the RPT data by means of a technique of nonlinear least squares fit. Latitudinal and local time dependences of these quantities are in good agreement with previous observations by other satellites. Their long term variations are examined from the data obtained from August 1978 to November 1979. Annual variation of T_e at the middle latitude is consistent with that by the incoherent scattering observations, but there is an asymmetry between the northern and southern hemispheres. The results also indicate that the annual variation has comparable amplitude to that of the semiannual variation around the magnetic equator. Global maps of observed quantities are depicted by using the spherical surface harmonic expansion method. Longitudinal dependences of these quantities in addition to latitudinal ones are evident in these maps. The distributions of T_e and M_i in low latitudes are related to each other, and they can be interpreted by the effects of the field-aligned interhemispheric plasma flows caused by atmospheric winds. (34 refs.)

78749 Observational results of the nighttime ion temperatures in the topside ionosphere by ISS-b. S.Miyazaki, E.Sagawa, H.Mori, T.Ogawa.

Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.449-55 (June 1982). In Japanese.

Global distributions of the nighttime ion temperatures in the topside ionosphere were obtained from Ionosphere Sounding Satellite (ISS-b) during August to December 1978. First, a computer processing method for analysis of the ion temperature from ion current of the retarding potential analyzer is described, secondly the observational results of the ion temperatures are described. The results indicate that ion temperatures at low latitudes are lower than that at high latitudes in general, but these latitudinal dependencies vary with longitude. The ion temperatures near the equator are high over the Pacific region compared with other regions. The nighttime ion temperatures in the low latitudes are gradually decreasing with time. (13 refs.)

78750 Observation of the ion composition by ionosphere sounding satellite. I.Iwamoto, E.Sagawa, T.Suiz.

Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.457-70 (June 1982). In Japanese.

Fairly complete latitudinal, diurnal and seasonal variations of the ion composition have been obtained from the observation by a Bennett ion mass spectrometer aboard the Ionosphere Sounding Satellite (ISS-b). The data used in this study were taken during the periods Aug. 1978 and Dec. 1979, which correspond to a solar maximum condition. The latitudinal profiles of the light ions, H^+ and He^+ , almost always show the mid-latitude trough structure. The trough is deeper in the nighttime than in the daytime. The distributions of He^+ have a marked depression at the geomagnetic equator. The equatorial depression of He^+ is also deeper in the nighttime. The seasonal variations of He^+ clearly show the winter bulge structure in the daytime but it disappears in the nighttime. The cause of the disappearance is attributed to the increased loss of He^+ in the winter night. Dependence of the mid-latitude trough position on K_p -index has been derived statistically from the invariant-latitudinal profiles of He^+ . (35 refs.)

78751 Characteristics of seasonal variations of O^+ ion density troughs in the nighttime topside ionosphere. S.Miyazaki, I.Iwamoto, H.Mori, E.Sagawa, T.Suiz, T.Ogawa.

Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.471-7 (June 1982). In Japanese.

Proton, helium ion and oxygen ion densities at about 1100 km in the topside ionosphere were observed by the Bennett type ion mass spectrometer on ISS-b during the maximum solar activity period from August 1978 to November 1979. Their global characteristics for seasonal and local time variations were studied by using the spherical surface harmonic expansion method. The results show that there exist distinguished O^+ ion density trough regions, and that the centers of main trough are located around the longitudes $0^\circ E$ and $180^\circ E$ respectively in northern summer and in northern winter, and around the latitudes $35^\circ \sim 70^\circ$ in the winter hemisphere. The main trough region changes its location with respect to the seasons by almost 180° in longitude and by moving toward the opposite hemisphere in winter, during rather short term around equinox conditions. The regions of relatively high and low O^+ ion density show good correlation with the regions of the eastward and westward declination of the earth's magnetic field in connection with the seasons.

A theoretical interpretation is examined such that the O^+ ion density trough is enhanced by the field-aligned plasma flow induced from neutral air wind pattern coupled with the Earth's magnetic field. The seasonal variation of O^+ ion density can be explained by the changes in the direction of the vertical plasma flow depending on the seasonal changes in the neutral air wind system. (14 refs.)

78752 HF radar Doppler studies of the effects of ionospheric motions on radio waves propagating in different modes. P.A.Bradley, A.J.Gibson, J.W.King (Rutherford Appleton Lab., Chilton, England). Third International Conference on Antennas and Propagation ICAP 83, Norwich, England, 12-15 April 1983 (London, England: IEE 1983), p.191-5 part 2

The magnitudes of the Doppler shifts and spreads imparted to HF sky-waves reflected from different ionospheric layers are indicated and it is shown that the correlation between the Doppler shifts imparted in different locations can be used to yield estimates of the speed and direction of movement of travelling ionospheric disturbances. The magnitude and periodicity of the Doppler shifts may also be used to infer the vertical magnitude and wavelength of the ionospheric corrugation associated with the disturbances. (2 refs.)

78753 Ionospheric aspect effect in the caustic zone. S.A.Namazov (Inst. of Radioengng. & Electronics, Acad. of Sci., USSR).

Third International Conference on Antennas and Propagation ICAP 83, Norwich, England, 12-15 April 1983 (London, England: IEE 1983), p.196-8 part 2

Investigations of ionospheric irregularities especially those using high power radio waves show that irregularities are field-aligned and have an anisotropic form. Radiowave scattering on these anisotropic irregularities has an aspect sensitivity and in the illuminated region (far from the caustic) takes place near the cone of the scattered radiation. Investigation of such field-aligned scattering (FAS) is of practical interest. In this report the results of Born approximation analysis are presented taking into account scattering intensity as a function of magnetic inclination, incident wave azimuth and Airy-function oscillations. (1 ref.)

78754 The determination of the propagation characteristics of very low frequency radio waves. K.E.Mowforth, T.B.Jones (Univ. of Leicester, Leicester, England).

Third International Conference on Antennas and Propagation ICAP 83, Norwich, England, 12-15 April 1983 (London, England: IEE 1983), p.199-203 part 2

A number of analytical techniques are available that enable the phase and amplitude of a propagating Very Low Frequency (VLF) wave to be determined as a function of distance for a given D-region model. Renewed interest in the prediction of VLF propagation characteristics has been stimulated by the development of the Omega radio navigation system, in which phase stability over great distances is an essential feature. The principal theoretical approaches currently employed are discussed. Propagation under a variety of conditions is considered and results from different techniques compared. Finally, one method is applied in a prediction of dawn phase changes over a long path at 10.2 kHz. (13 refs.)

94.30 PHYSICS OF THE MAGNETOSPHERE (for planets, see 96.30)

78755 Estimation of wave vector characteristics. S.D.Shawhan (Dept. of Phys. & Astron., Univ. of Iowa, Iowa City, IA, USA). *Adv. Space Res. (GB)*, vol.2, no.7, p.31-41 (1982).

In the realistic case of multiple electromagnetic plasma wave sources and multiple propagation paths, auto-correlation and cross-correlation products of the six wave components can be utilized to fit model parameters for the wave normal vector and Poynting vector distribution functions. With the complete wave vector characteristics, the wave mode can be identified, the index of refraction derived and the wave ray traced back towards the wave source region. Plasma wave instrumentation suitable for estimating some wave vector characteristics has been carried on satellites starting with FR-1 in 1964 and has evolved in various configurations on OGO-5, Injun-5, GEOS, Voyager, ISEE, Dynamics Explorer and the proposed OPEN spacecraft. Plasma wave research developments are considered. (24 refs.)

78756 Computer constructed imagery of distant plasma interaction boundaries. E.W.Greenstadt, H.D.Schurr, R.K.Tsugawa (TRW Space & Technol. Group, Advanced Products Lab., Appl. Technol. Div., One Space Park, Redondo Beach, CA, USA). *Adv. Space Res. (GB)*, vol.2, no.7, p.163-8 (1982).

Computer constructed sketches of plasma boundaries arising from the interaction between the solar wind and the magnetosphere can serve as both didactic and research tools. In particular, the structure of the Earth's bow shock can be represented as a nonuniform surface according to the instantaneous orientation of the IMF, and temporal changes in structural distribution can be modeled as a sequence of sketches based on observed sequences of spacecraft-based measurements. Viewed rapidly, such a sequence of sketches can be the basis for representation of plasma processes by computer animation. (5 refs.)

78757 Field-aligned current density versus electrical potential characteristics for magnetosphere flux tubes. J.Lemaire, M.Scherer (Inst. for Space Aeronomy, Brussels, Belgium). *Ann. Geophys. (France)*, vol.1, no.1, p.91-6 (Jan.-Feb. 1983).

The field-aligned current density (J_{tot}) is a non-linear function of the applied potential difference (ϕ) between the ionosphere and the magnetosphere. This non-linear function is calculated for plasma boundary conditions typical in a dayside cusp magnetic flux tube. The J -characteristic of such a flux tube changes when the temperatures of the warm magnetospheric electrons and of the cold ionospheric electrons are modified; it changes also when the relative density of the warm plasma is modified; the presence of trapped secondary electrons changes also the J -characteristic. The partial currents contributed by the warm and cold electrons, and by warm and cold ions are illustrated. (9 refs.)

78758 Electrostatic waves in the magnetosphere. D.C.Agarwal, D.C.Pande (J.K. Inst. of Appl. Phys. & Technol., Univ. of Allahabad, Allahabad, India).

Indian J. Theor. Phys., vol.29, no.3, p.247-60 (Sept. 1981).

Electromagnetic waves have been observed in the magnetosphere both with the OGO 5 and the topside sounder Alouette 2. These waves were detected during VLF electric field observations, as half harmonic waves. The authors present a critical examination of the results. There are a wide variety of instabilities in a collisionless plasma which could provide a turbulent wave spectrum in the magnetosphere. Such electrostatic instabilities responsible for the generation of electrostatic waves in the magnetosphere are reviewed; the triggering and saturation mechanisms of such waves are also studied. (27 refs.)

78759 Terrestrial magnetic storms. J.Untiedt (Westfälischen Wilhelms-Universität, Münster, Germany).

Phys. Bl. (Germany), vol.39, no.5, p.111-16 (May 1983). In German.

Gives explanations for magnetic variations, also known as magnetic storms, and defines the parameters of such storms as SD variations (solar and disturbed), AE effects (auroral aerolets), DST variations (disturbed and storm time) in terms of ionospheric electric currents. Describes measurements by MAGSAT and by the Bear Island Observatory and proposes models for magnetic storm systems, based on currents to produce equivalent magnetic fields. Finally, effects of solar wind are quantified. (14 refs.) G.M.E.

78760 Does IMF B_z induce the cusp field-aligned currents? F.Primdahl, F.Spangshov (Danish Space Res. Inst., Lyngby, Denmark). *Planet. & Space Sci. (GB)*, vol.31, no.4, p.363-7 (April 1983).

A well established correlation exists between the IMF B_z component and the cusp field-aligned and horizontal currents (Wilhelm et al., 1978). The northern and southern cusp currents may be parts of one large scale current system (D'Angelo, 1980) flowing mainly at the magnetopause and driven by the z -component of the solar wind electric field. Primdahl and Spangshov (1981) suggested that the large scale current system seems to shield out the IMF B_z from the interior of the magnetosphere. The authors propose that the currents are induced by the change in sign of B_z at the IMF sector boundary crossings, and argues that the time constant for the decay of the currents may be one week or larger. Experimental tests are proposed to demonstrate the feasibility of and possibly distinguish between the mechanisms. (10 refs.)

78761 The effect of a meridional $E \times B$ drift on the thermal plasma at $L=1.4$. G.J.Bailey (Dept. of Appl. & Computational Maths., Univ. of Sheffield, Sheffield, England).

Planet. & Space Sci. (GB), vol.31, no.4, p.389-409 (April 1983).

A fully time dependent mathematical model of the thermal plasma at $L=1.4$ is described. In the mathematical model account is taken of a quiet-time $E \times B$ drift in the meridional plane. Atmospheric conditions appropriate to the equinox at sunspot minimum and at sunspot maximum are considered. Results of the model calculations are presented. Emphasis is placed on the effects on the thermal plasma of a quiet-time $E \times B$ drift in the meridional plane. A comparison of the model calculations which include an $E \times B$ drift with those in which there is no $E \times B$ drift shows that an $E \times B$ drift significantly affects the plasma concentration and temperature distributions during the day at both sunspot minimum and sunspot maximum; the effects at night are very small. (41 refs.)

78762 Polarisation characteristics of Pi 2 pulsations and implications for their source mechanisms: influence of the westward travelling surge. J.C. Samson, G. Rostoker (Dept. of Phys., Univ. of Alberta, Edmonton, Alberta, Canada).

Planet. & Space Sci. (GB), vol.31, no.4, p.435-58 (April 1983).

Expands the results of Rostoker and Samson (1981), who noted that there are two latitudinal areas of Pi 2 localisation near the high latitude, substorm enhanced electrojets. The detailed study presented outlines the morphology of the polarisations of the Pi 2's in and near the westward travelling surge. There are two latitudinal areas of Pi 2 localisation. A poleward Pi 2 predominates within the surge and to the East, whereas an equatorward Pi 2 predominates equatorward and West of the surge. These Pi 2 localisations appear to correlate with the substorm enhanced westward and eastward electrojets respectively. The elliptical polarisation of the Pi 2's is most likely caused by azimuthal (longitudinal) expansion of the field-aligned currents in the surge, in association with reflection of the field-aligned current pulses from northern and southern high latitude ionospheres. (30 refs.)

78763 Local time asymmetry in the characteristics of Pc 5 magnetic pulsations. K. Yumoto, T. Saito (Onagawa Magnetic Obs., Tohoku Univ., Sendai, Japan), T. Sakurai.

Planet. & Space Sci. (GB), vol.31, no.4, p.459-71 (April 1983).

The wave characteristics of Pc 5 magnetic pulsations are analysed with data ofOGO-5, ISEE-1 and -2 satellites. The toroidal modes of Pc 5 pulsations are observed at a higher magnetic latitude in the dawnside outer magnetosphere. The compressional and poloidal modes of Pc 5 pulsations are mostly observed near the magnetic equator in the duskside outer magnetosphere. This LT asymmetry in the occurrence of dominant modes of Pc 5's in space is explained as is the asymmetric behaviour of Pc 5 pulsation activity on the ground across the noon meridian. (65 refs.)

78764 Propagation properties of hydromagnetic waves in a hot plasma and right-hand polarised PC 1 and PC 5. T. Namikawa, H. Hamabata, Y. Hosoya (Dept. of Phys., Osaka City Univ., Osaka, Japan).

Planet. & Space Sci. (GB), vol.31, no.4, p.473-81 (April 1983).

Propagation characteristics of hydromagnetic waves in a hot plasma are investigated and the results are used for the interpretation of Pc 1 and Pc 5 with right-hand polarisation guided along the geomagnetic field line. (33 refs.)

78765 Three-dimensional ray tracing of low frequency electromagnetic waves in the Earth's magnetosphere. V.I. Aksenov, A.V. Moshkov (Inst. of Radioengng. & Electronics, Acad. of Sci., Moscow, USSR).

Third International Conference on Antennas and Propagation ICAP 83, Norwich, England, 12-15 April 1983 (London, England: IEE 1983), p.204-8 part 2

In the present work a procedure of numerical integration of a set of differential equations describing three-dimensional ray tracing of LF electromagnetic waves in a spherically inhomogeneous multicomponent magnetospheric plasma is proposed. The developed procedure is used to investigate an influence of ray deflection of a magnetic meridian plane on such basic characteristics of LF signal as group delay time, arrival latitude and longitude. A possibility of propagation of LF signals in three-dimensional geomagnetic ducts (enhancements of ionization which are geomagnetic field aligned) is also analysed, an influence of wave normal declination of a magnetic meridian plane and duct characteristics on path pattern and conditions of wave trapping into duct being considered. 78766 Isotopic anomalies among solar energetic particles: contribution of preacceleration in collapsing magnetic neutral sheets. D.J. Mullan (Bartol Res. Found., Univ. of Delaware, Newark, DE, USA).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.385-95 (1 May 1983).

Anomalous abundances of elements among solar flare particles have previously been interpreted in terms of a contribution from preacceleration in collapsing magnetic neutral sheets. The isotopic anomalies which are predicted by this preacceleration mechanism are examined. Enhancements of neutron-rich isotopes are found but the enhancements are not a monotonic function of the mass ratio. Thus, enhancement of $^{22}\text{Ne}/^{20}\text{Ne}$ need not be accompanied by any significant enhancements in, say, $^{18}\text{O}/^{16}\text{O}$ or $^{26}\text{Mg}/^{24}\text{Mg}$. High temperatures (such as those in flares) favor enhancement of $^{22}\text{Ne}/^{20}\text{Ne}$ as the dominant isotopic anomaly. These results may help to account for some of the observed isotopic anomalies among solar energetic particles. (29 refs.)

(Yamanashi Medical Coll., Yamanashi, Japan).

J. Phys. Soc. Jpn. (Japan), vol.52, no.5, p.1503-4 (May 1983).

Day-to-day variations of cosmic-ray-produced neutron fluxes near the Earth's ground surface are measured by using three sets of paraffin-moderated BF₃ counters, which are installed in different locations: 3 m above ground, ground level and 20 cm under ground, respectively. Neutron flux decreases observed by these counters when snowcover exists show that there are upward-moving neutrons, that is, ground albedo neutrons near the ground surface. The amount of albedo neutrons is estimated to be about 40% of total neutron flux in the energy range $1-10^6$ eV. (6 refs.)

78768 Comment on the cosmic ray energy spectrum in the light of results from atmospheric Cerenkov studies. R.W. Clay, A.G. Gregory, P.R. Gerhardt, G.J. Thornton (Phys. Dept., Univ. of Adelaide, Adelaide, Australia).

Aust. J. Phys. (Australia), vol.36, no.2, p.227-33 (1983).

New information has become available on the development of cosmic ray showers in the atmosphere. This information is used to show that the energy spectrum of cosmic rays must exhibit more pronounced structure than previously thought at energies of about 10^{16} eV. Possible interpretations of this structure are discussed. (19 refs.)

(see also 96.60 Solar physics)

78771 A numerical method based on the Fourier-Fourier transform approach for modeling 1-D electron plasma evolution. A.J. Klimas (Lab. for Extraterrestrial Phys., NASA/Goddard Space Flight Center, Greenbelt, MD, USA).

J. Comput. Phys. (USA), vol.50, no.2, p.270-306 (May 1983).

A numerical method for studying one-dimensional electron plasma evolution under typical interplanetary conditions is presented. The method uses the Fourier-Fourier transform approach to a plasma model which is a generalization of the electrostatic Vlasov-Poisson system of equations. Conservation laws which are modified to include the plasma model generalization and also the boundary effects of nonperiodic solutions are given. A new conservation law for entropy in the transformed space is introduced. These conservation laws are used to check the accuracy of the numerical solutions. A discretization error analysis is given. Two numerical instabilities and the methods used for their suppression are discussed. Several solution examples are presented. Two of these are comparisons with earlier independent results; the comparison is favorable. A third example is also discussed which uses an interplanetary observation of a bump-on-tail unstable velocity distribution as initial data. It

is shown that in interplanetary plasma conditions the bump-on-tail instability leads to significant excitation of plasma oscillations at the Bohm-Gross frequency and its second harmonic. An explanation of the second harmonic excitation in terms of wave-wave coupling during the growth phase of the instability is given. (26 refs.)

(see also 87.65 Aerospace biophysics and medical physics)

78772 The MAGION sub-satellite experiment. P.Triska, F.Jiricek, J.Vojta, A.Czapek (Geophys. Inst., Czechoslovak Acad. Sci., Prague, Czechoslovakia). *Adv. Space Res. (GB)*, vol.2, no.7, p.53-6 (1982).
MAGION (1978-099C) was launched as a part of the Interkosmos 18 satellite and separated from this parent spacecraft on 14 November 1978, with the aim of studying the spatial structure of ELF-VLF phenomena using simultaneous measurements of the two near-spaced satellites. The MAGION experiment went on for almost three years, till the decay date of September 10, 1981. A description of the experiment is given and some new aspects of the satellite-subsatellite experimental technique for near-space research are indicated. (9 refs.)

78773 A payload for the study of electric fields and electron density in the equatorial region. S.Pal, S.Prakash, Y.B.Acharya, R.N.Misra (Phys. Res. Lab., Ahmedabad, India). *Adv. Space Res. (GB)*, vol.2, no.7, p.57-9 (1982).
A rocket borne payload for simultaneous measurement of the electric field along and perpendicular to the rocket spin axis and the electron density in the medium was developed and flown from Thumba ($8^\circ 31'N$, $0^\circ 47'S$ dip) onboard two Centaure rockets for the study of plasma dynamics in the equatorial E-region. The arrangement of sensors in this payload allows near continuous measurements of some of these parameters to be made. (3 refs.)

78774 High resolution thermal plasma measurements aboard the Aureol 3 spacecraft. C.Beghin (CRPE, CNRS, Orleans, France), J.J.Berthelot, R.Debrie, Yu.I.Galperin, V.A.Gladyshev, N.I.Massevitch, D.Roux. *Adv. Space Res. (GB)*, vol.2, no.7, p.61-6 (1982).
Two instruments using different techniques have been designed for making thermal electron and ion measurements performed aboard the AUREOL 3 satellite with the Soviet-French project ARCAD 3. The ISOPROBE gives precise measurements of electron density and temperature and their fluctuations with a high time resolution by using the mutual impedance technique. The ion mass-spectrometer DYCION performs measurements of number density, temperature and three-component velocity vector of the three major ionospheric thermal ions H^+ , He^+ and O^+ . After a brief description of the instruments, a few preliminary results are given. (15 refs.)

78775 An instrument for rapidly measuring plasma distribution functions with high resolution. C.W.Carlson (Space Sci. Lab., Univ. of California, Berkeley, CA, USA), D.W.Curtis, G.Paschmann, W.Michael. *Adv. Space Res. (GB)*, vol.2, no.7, p.67-70 (1982).
A new instrument which can rapidly measure plasma particle distribution functions has been developed based upon innovations in electrostatic analyzer design and position sensitive particle detection. The new analyzer uses a quadrupole geometry, but has a completely uniform 360° fan-shaped field of view. The polar angular distribution of entering particles is spatially imaged onto a position sensitive detector at the annular exit aperture after a deflection through 90° . Several methods of position sensitive detection have been successfully used in conjunction with this analyzer. The simplest is individual channel multipliers spaced around the annular exit. Microchannel plate electron multipliers permit greater position resolution to be obtained, and a detector using microchannel plates followed by a resistive anode image converter obtains angular resolution of about one degree, 360 individual angle pixels. Instruments of this type were flown on a sounding rocket in early 1982 and will be included on the Giotto comet mission and the AMPTE ion release module. (4 refs.)

78776 An instrument for total ion drift velocity measurements aboard the 'INTERCOSMOS-BULGARIA-1300' satellite. L.G.Bankov (Central Lab. for Space Res., Bulgarian Acad. of Sci., Sofia, Bulgaria), M.N.Gousheva, B.B.Kirov, N.G.Bankov, Yu.Shulchishin, K.Greshnev, N.Nikolaeva. *Adv. Space Res. (GB)*, vol.2, no.7, p.71-4 (1982).
The ion driftmeter, ID-1, aboard this satellite was intended to measure ion density irregularities, the ion drift velocity and photoelectron fluxes. The purpose of this paper is to present a brief description of the ID-1 instrumentation and to show the first results obtained from the flight instrument. (2 refs.)

78777 Instrumentation and data systems for high-time resolution study of space plasma shocks. V.M.Balebanov (Space Res. Inst., Acad. of Sci., Moscow, USSR), O.L.Vaisberg, E.M.Vasiliev, G.N.Zastenko, V.P.Evdokimov, E.G.Eroshenko, L.V.Pesotski, V.F.Babkin, S.Fisher, Z.Nemechek, Ya.Shafrankova. *Adv. Space Res. (GB)*, vol.2, no.7, p.75-9 (1982).
Deals with the principal methods of achieving high-time resolution measurements for the study of fine structure of shocks and other discontinuities in space plasmas. In the measurements of ion energy spectra, time resolution of about 1 s has been obtained. The Soviet-Czechoslovak INTERSHOCK project will obtain temporal resolution better than 0.1 s in the measurement of plasma parameters. (10 refs.)

78778 Particle and optical measurements aboard the AUREOL 3 spacecraft (ARCAD 3 project). A—The particle experiments. B—Optical measurements. J.M.Bosquet (CESR, CNRS, Toulouse Univ., Toulouse, France), Yu.I.Galperin, R.A.Kovrazhkin, Yu.N.Ponomarev, H.Reme, J.A.Sauvaud, F.K.Shuiskaya. *Adv. Space Res. (GB)*, vol.2, no.7, p.81-5 (1982).
CESR Toulouse-1K1 Moscow particles instrument package aboard the Aureol-3 satellite which consists of a complete set of charge particle spectrometers which measure electron and ion fluxes from 15 eV to 25 keV in 128 steps and in 11 directions. In addition, 4 channel spectrometers (2 electron and 2 ion channels in parallel) allow high time resolution measurements (up to 10 msec) with onboard calculation of auto and cross correlation functions. For higher energies (40-280 keV), solid-state spectrometers are used to measure electron and proton fluxes in 4 channels in parallel. Two Geiger counters are used for the determination of the trapping boundaries. Two mass-energy ion spectrometers (1 to 32 AMU, 0.02-15 keV) are placed with viewing angles which allow a distinction between nearly isotropic auroral proton precipitation and conical beams accelerated in the auroral ionosphere. Auroral and airglow photometry is performed aboard the AUREOL-3 satellite by a set of 3 parallel directed photometers with tiltable interference filters. Examples of data from inflight measurements using the instruments are presented and briefly discussed. (9 refs.)

78779 Advances in auroral imaging from space. C.D.Anger (Dept. of Phys., Univ. of Calgary, Calgary, Alberta, Canada). *Adv. Space Res. (GB)*, vol.2, no.7, p.97-105 (1982).
A new type of imaging instrument being built in Canada for the Swedish Viking satellite will employ a two-dimensional CCD array detector which is fibre-optically coupled to a microchannel plate intensifier. It will produce images of low level auroral emissions at the rate of one image per spin of the satellite (20 seconds). The instrument operates in the vacuum ultraviolet and uses a fast inverse Cassegrain optical system. Charge is shifted in the CCD imaging array in synchronism with the moving image so that exposure times of approximately one second will be achieved. (27 refs.)

78780 Application of numerical Fourier transformation on measurements made on board rotating spacecraft. R.Grabowski, B.Bosch, H.Wolf (Fraunhofer-Inst. fur Phys. Messtech., Freiburg, Germany). *Adv. Space Res. (GB)*, vol.2, no.7, p.169-72 (1982).
Signals obtained on board rocket payloads or satellites are often 'spin modulated'. The relevant information is then found within the envelope and the phase of the signal. The most efficient method of extracting this information is the numerical Fourier analysis. The efficiency and the accuracy of this technique are demonstrated. (5 refs.)

78781 Sond-R, an instrument for vertical probing of ionospheric plasma by means of CLP on board of a geophysical rocket. T.N.Ivanova, S.M.Halova (Central Lab. for Space Res., Bulgarian Acad. of Sci., Sofia, Bulgaria). *C.R. Acad. Bulg. Sci. (Bulgaria)*, vol.36, no.3, p.345-8 (1983).
The Sond-R instrument measured the local parameters of the space plasma near the irretrievable container of the geophysical rocket Vertical 10 (fired on December 21, 1981) at a height of 1505 km: electron density (N_e), temperature of electrons (T_e), function of their distribution, and, in particular, potential of body (V_0), as well as ion density (N_i) and ion mass composition (M_i). The sensitive element (sensor) is a onesidedly protected cylindrical Langmuir probe (CLP) with a 120-mm long collector and a 2-mm diameter, let out on a rod outside the container. The sawtooth voltage of the sweep (U) produced in the instrument is directly transmitted to the probe's protected electrode or to the common rim of the DC amplifier (DCA) insulated from the body. The dependence of the DCA-recorded probe current (I) on U gives the probe volt-amp characteristic ($I(U)$), from which the parameters of the ionospheric plasma are determined by mathematical processing (on board and ground). (2 refs.)

78782 The microgravity payload for the first Eureka mission. G.Seibert (Space Transportation Systems, Paris, France), K.Fuhrmann. *ESA Bull. (France)*, no.34, p.6-12 (May 1983).
From a user viewpoint, a gap exists between the short-duration research opportunities offered by Spacelab and the permanent space stations planned for the 1990s. It is shown how this gap can be filled by exploiting the deployment and retrieval capability of the Space Shuttle, Eureka, a retrievable autonomous platform. (no refs.)

78783 IRAS, the Infrared Astronomical Satellite. *Nature (GB)*, vol.303, no.5915, p.287-91 (26 May 1983).
The Infrared Astronomical Satellite, launched on 26 January 1983, is providing the first map of the entire IR sky. This article describes the operation and preliminary results of the IRAS mission. (no refs.)

78784 Operation and experimental results of ionosphere sounding satellite-b (ISS-b, UME-2). I. Outline of ISS-b project. Y.Hakura. *Rev. Radio Res. Lab. (Japan)*, vol.28, no.146, p.149-54 (June 1982). In Japanese.

The project of ISS (Ionosphere Sounding Satellite) has been promoted under the cooperation of the Radio Research Laboratories (RRL), Ministry of Posts and Telecommunications, and the National Space Development Agency of Japan (NASDA). The main objective of the satellite is to carry out observations of the worldwide distributions of ionospheric parameters and radio noises in conjunction with the global survey of radio environment necessary for improvement of efficiency on radio communications. The spacecraft installs the following four mission apparatus, (1) a digital swept frequency sounder for sounding of the topside ionosphere (TOP), (2) narrow band HF receivers for radio noise measurement (RAN), (3) a retarding potential trap for plasma measurement (RPT), and (4) the Bennett type ion-mass spectrometers for detecting positive ion composition (PIC). In observation modes, the four missions are executed sequentially in every 64 sec. The regular stage of ISS-b observation has been carried out by the RRL since April 24, 1978. With the routine observation performed for almost three years, a great deal of data over the entire global regions have been accumulated. The author summarizes the operational status and the experimental results of this most successful environmental monitoring satellite. (no refs.)

78785 Topside sounder onboard ISS-b. R.Nishizaki, N.Matsuura, A.Takahira. *Rev. Radio Res. Lab. (Japan)*, vol.28, no.146, p.155-65 (June 1982). In Japanese.

The ISS-b carries a HF pulse radar system so called a digital topside sounder for the execution of the TOP mission. The basic functions of the system are to transmit the pulsed radio wave of swept frequency and to receive echoes returned to the satellite after reflection in the ionosphere and at the ground. In the TOP mission there are two modes provided: TOP-A and TOP-B, of which are allocated times of 8 and 16 seconds, respectively, among 64 seconds of the time for an observational sequence. For TOP-A observation, the lowest frequency of the interference signals from the ground, f_u and the ionospheric critical frequency, f_c are determined automatically by the onboard preprogrammed logic circuit. Unfortunately, the operational test conducted after the

launch confirmed the malfunction of this logic circuit. The detailed examination revealed that the malfunction arises from misidentification of the internally produced signal at around 0.5 MHz of the frequency as if it is the interference from the ground. Furthermore, the obliquely propagating interference below the critical frequency and the intense noise frequently observed in the polar region also makes it difficult to make the TOP-A observation. The authors describe the characteristics of the antenna system, the transmitter and the receiver, and discusses the problems of the sounder system. (9 refs.)

78786 Characteristics of the radio noise receiving equipment. C.Kato, H.Kuriki, M.Kotaki, H.Suguchi.
Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.167-74 (June 1982). In Japanese.

Describes the characteristics of the radio noise measurement equipment on-board the Ionosphere Sounding Satellite, ISS-b, which was launched on February 16, 1978 into a near-circular orbit at an altitude of about 1100 km. The radio measurement equipment is composed of four HF receivers of which center frequencies are, in order to avoid interferences, fixed in the guard bands of the standard frequency transmission of 2.5, 5, 10, and 25 MHz, respectively. Each receiver adopted a straight type amplifier, instead of conventional frequency conversion type, so as to exclude non-linear distortion. The band width of the receiver is limited to about 1 kHz by using the monolithic crystal filter. The overall dynamic range of the receiver covers more than 60 dB and it can respond to the violent change of field strength of radio waves radiated from lightning discharges. (4 refs.)

78787 The ISS-b retarding potential analyzer. H.Mori, S.Miyazaki, E.Sagawa, T.Ogawa.
Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.175-82 (June 1982). In Japanese.

A retarding potential analyzer with spherical electrodes is mounted on the ISS-b. The primary objective is to measure the electron and ion densities and the electron and ion temperatures in the ionosphere. The authors give a description of the retarding potential analyzer. (3 refs.)

78788 Ion mass spectrometer on ionosphere sounding satellite (ISS-b). I.Iwamoto, N.Fugono, T.Suitz.
Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.183-95 (June 1982). In Japanese.

An ion mass spectrometer was flown on the Ionosphere Sounding Satellite (ISS-b), which was put into a nearly circular orbit with an inclination of 70 degrees and an altitude of about 1100 km. The observations of global distribution of the positive ions are assured by two identical Bennett spectrometer tubes which are mounted at the top- and bottom-covers of the spacecraft. The Bennett tube is constructed from fifteen planar grids and works as a RF linear accelerator. The mass scan range is 1 to 20 AMU and major positive ions such as H^+ , O^+ and He^+ can be observed. The absolute densities of the positive ions are deduced by in-flight calibration method. In addition to detailed description of the instrument, brief accounts of the observational results are also given. (12 refs.)

78789 On the structure and functions of the ISS-b satellite control systems. K.Muranaga, M.Uratsuka, M.Shikatanai.
Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.197-203 (June 1982). In Japanese.

The construction of Satellite Control Systems and Center building for ISS-b at Kashima Branch RRL, started in July 1970 and was completed in July 1975. All the sub-systems in the Satellite Control Center are controlled by the computer and so they conduct automatically relevant operation like satellite tracking, telemetry data reception and command transmission according to operational pass schedule. As a result of this computer system CSSC, Computer System for Satellite Control, it could be realized to obtain accurately and efficiently the observational data from ISS-b and also to reduce manpower to some extent. The outline of the structure and functions of ISS-b Satellite Control System at Kashima station is described, especially in the facilities based on the process computer control systems. (3 refs.)

78790 Scheduling of ISS-b operations. T.Ide, K.Aikey.
Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.205-18 (June 1982). In Japanese.

The ISS-b spacecraft is capable of storing the observed data with the aid of an on-board tape recorder with a maximum recording time slightly longer than the satellite orbital period. In addition to this recording capability, the delay command function controlling the start time of data recording enables choice of satellite passes so that the observational points are distributed over the Earth as uniformly as possible, successfully achieving worldwide observations of the ionospheric parameters and radio noises. The stored data are telemetered to a ground station through a fast playback mode at the speed of 26 times faster than the recording speed. The authors describe the operational scheduling for ISS-b and the computer algorithm used for actual operations at Kashima and Ottawa ground stations. The basic policy of the scheduling, in general, can be applied to the mapping purposes with the limited number of satellites and TT&C (Telemetry, Tracking and Command) stations. (5 refs.)

78791 Operations of ISS-b at Kashima station and their result. M.Uratsuka, T.Yanagiya, E.Kawai, S.Iguchi.
Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.219-38 (June 1982). In Japanese.

The most active period of ISS-b at Kashima station RRL as regards obtaining the experimental data was the first two years since the beginning of the regular stage operation in April 1978. The authors state some operation modes and processes to control the ISS-b, e.g. the tracking, telemetry and command. Also they discuss the matters and characteristic variations encountered in the operations, e.g. solar cell's electric power, battery voltage, Sun spin angle, temperature of equipment on board, etc. (7 refs.)

78792 Orbit and attitude of ISS-b. S.Yamamoto, F.Sawada.
Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.239-47 (June 1982). In Japanese.

Accurate determination of the position and the attitude of ISS-b is necessary for the operation and analysis of the data obtained. Attempts to determine the orbit and the attitude of ISS-b were successfully made at Kashima Station. The attitude determination algorithm has been used on a routine basis. The authors outline the methods. Some features of long-term variations in the orbit and attitude determined by the methods are also discussed. (6 refs.)

78793 Operation of primary processing and data analysis system for ISS. M.Nagayama, S.Igi, M.Yamanishi.
Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.249-90 (June 1982). In Japanese.

Satellite Operation Planning and Data Analysis System (SODAS) completed in 1976 has been utilized favorably for the operation of ISS-b and for the subsequent data processing and analysis. The authors describe the four sub-systems included in SODAS prepared for the purposes of carrying out the primary processing and analysis of the ISS-b data. The subsystems include

the data communication system for the satellite data transmission in real time basis and for exchanging information via 7 GHz microwave link between the headquarters of RRL and the earth station at Kashima. Discusses also the satellite data monitoring system for acquiring information of the four missions and the condition of the electric power and the attitude immediately, the satellite data processing system to make digital data tapes for experimenters' effectual utilization, and the online ionogram analysis system to scale critical frequency (f_oF_2) and resonance frequencies, and to get $N(h)$ profiles from the satellite data. (5 refs.)

78794 On the application of housekeeping data to ISS-b operations. R.Nishizaki, A.Takahira, T.Ide.
Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.291-308 (June 1982). In Japanese.

Since the attitude of the ISS-b is solely governed by spin stabilization, the satellite conditions such as thermal structure and power supply vary in a complicated manner. Hence, predictions of the satellite conditions are necessary so as to make the satellite operations under optimum scheduling. By using the HK data acquired after injection into the orbit, the empirical equations were obtained for expressing the long term variations of the Sun-spin angle, the ecliptic ratio, the generated power and the temperatures of various parts of the spacecraft equipments including the battery and the magnetic tape recorder as functions of the revolution number or the date. These equations have been used to predict the satellite conditions which must be taken into consideration in the scheduling of the satellite operations. (no refs.)

78795 Automation of satellite control system and its effectiveness in actual operation. T.Iida, M.Uratsuka, K.Sawaji.
Rev. Radio Res. Lab. (Japan), vol.28, no.146, p.309-13 (June 1982). In Japanese.

Describes purposes and outlines the fully automated system for Ionosphere Sounding Satellite ISS-b control, and shows that the automation increases the successful pass rate from 88% to 97% and that it can reduce the number of operators from two to one, compared with the semiautomated system. 78798 Gravitational three-body problem in 120 deg axial coordinates. W.E. Bleick (Naval Postgraduate School, Monterey, CA, USA). *J. Guid. Control & Dyn. (USA)*, vol.6, no.2, p.124-8 (March-April 1983). Recently (1982) the author introduced a symmetrical system of distance coordinates for studying the planar motion of a three-body system of point masses in its internal degrees of freedom. This work, devoted largely to the small vibration problem, is expanded to give the details of a complete numerical solution of the gravitation problem, including the three angular degrees of freedom. The three coordinate axes pass through the masses with the positive halves intersecting at angles of 120 deg with each other at a moving origin. The distance coordinates are taken as the signed distances of the masses from the moving origin. If the angular orientation of the coordinate axes is defined by the Euler angles, an attempt to determine these angles by integrating their time rates of change fails because of singularities. It is shown that such singularities are avoided by the use of Rodrigues' orthogonal matrix to specify the angular orientation. The Lagrange equations are solved for the appropriate time derivatives, separating the distance variables from themselves and the angular velocities, thus making possible a simple computer numerical solution. (4 refs.)

78799 Periodic motion of a satellite under the gravitational attraction of a rotating rigid body. A.H. Borham. *Vestn. Mosk. Univ. Ser. I (USSR)*, no.2, p.74-8 (March-April 1983). In Russian.

Proves the existence of a family of periodic solutions for the problem of particle motion under the gravitational action of a homogeneous three-axial ellipsoid close to a sphere of the same volume and rotating uniformly about the smallest axis. (5 refs.)

95.30 FUNDAMENTAL ASPECTS OF ASTROPHYSICS

78800 The equilibria of rotating, isothermal clouds. I. Method of solution. S.W. Stahler (Center for Radiophys. & Space Res., Cornell Univ., Ithaca, NY, USA).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.155-64 (1 May 1983).

In an effort to resolve the current controversy in dynamical models of rotating protostellar collapse, a detailed study has been made of the axisymmetric equilibrium configurations for differentially rotating, isothermal clouds. The physical assumptions underlying the calculation are stated and the numerical technique outlined. The clouds are assumed to have the angular momentum distribution or rigidly rotating, uniform-density spheres of the same mass. Magnetic and viscous effects are neglected. The computational method is designed to handle highly flattened structures, should they arise, and to yield numerical values of the density. (30 refs.)

78801 The equilibria of rotating, isothermal clouds. II. Structure and dynamical stability. S.W. Stahler (Center for Radiophys. and Space Res., Cornell Univ., Ithaca, NY, USA).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.165-84 (1 May 1983).

For pt.1 see ibid., vol.268, no.1, p.155-64 (1983). Numerical results are presented for the structure of differentially rotating, isothermal clouds. The equilibria can be characterized by two parameters: a dimensionless mass M and the rotational parameter β ($0 \leq \beta \leq 1/2$). At any fixed β , there exists a critical mass $M^*(\beta)$ which is marginally dynamically unstable to axisymmetric perturbations. Stability is diagnosed by investigating the change in M as a function of density contrast at fixed β . This 'static method' is proved rigorously for the present case. The structure of unstable equilibria with $M < M^*(\beta)$ is displayed. The marginally unstable normal modes of oscillation at the critical masses are obtained numerically over the full range of β . Similar cases of instability in the fundamental mode are shown to exist in nonrotating polytropes bounded by a finite external pressure. Finally, a comparison of the stability results for isothermal clouds with the dynamical collapse calculations suggests a simple interpretation for the latter. Ringlike collapses or other runaway situations are obtained with initial conditions such that $M > M^*(\beta)$. Stable, disklike configurations are obtained for subcritical masses. (34 refs.)

78802 Nonlinear propagation of hydromagnetic waves in high-beta plasmas. P.K. Shukla (Inst. für Theoretische Phys., Ruhr-Univ. Bochum, Bochum, Germany).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.396-7 (1 May 1983).

Nonlinear interaction of hydromagnetic waves with slow plasma motion is considered in high- β plasmas. The possibility of modulational instability is investigated. Relevance to the propagation of cosmic rays in the interstellar medium is discussed. (11 refs.)

78803 Effect of screening due to free mobile charges on the binding energy of an H^- ion. D.E. Phelps (Air Force Wright Aeronautical Labs., Wright Patterson AFB, OH, USA), K.K. Bajaj.

Astrophys. J. (USA), vol.268, no.1, pt.1, p.447-50 (1 May 1983).

A calculation of the binding energy of a negative hydrogen ion (H^-), defined as the energy required to remove one of the two electrons from the H^- ion to infinity in the presence of other free mobile charges, is reported. The effective interactions between the constituent particles of the H^- ion are assumed to be described by Dingle-Mansfield potentials. This potential is valid for a Fermion gas of an arbitrary degeneracy. The variation of the binding energy of an H^- ion as a function of the screening parameter δ is calculated, using a variational approach. It is shown that the binding energy of an H^- ion goes to zero for $a\delta = 0.87$, where a is the Bohr radius. The binding energy of a hydrogen atom itself in the presence of free mobile charges goes to zero for $a\delta = 1.2$. The relative significance of these two values is discussed. (14 refs.)

78804 Simulation models for the evolution of cloud systems. I. Introduction and preliminary simulations. W.A. Pumphrey, J.M. Scalo (Dept. of Astron., Univ. of Texas, Austin, TX, USA).

Astrophys. J. (USA), vol.269, no.2, pt.1, p.531-59 (15 June 1983).

The evolution of systems of interacting gas clouds is investigated, with application to protogalaxies in galaxy clusters, proto-globular clusters in galaxies, and protostellar fragments in interstellar clouds. The evolution of these systems can be parameterized in terms of three dimensionless quantities: the number of clouds, the volume filling factor of clouds, and the fraction of the mass of the system in clouds. The authors discuss the range of parameter space in which direct cloud collisions, tidal encounters, interactions of clouds with ambient gas, cloud collapse, cloud orbital motion due to the gravitational acceleration of the rest of the system, and cumulative long-range gravitational scatterings are important. The only practical approach to quantitative study of cloud systems is statistical modeling, whose chief limitation is the restricted availability of realistic interaction cross sections, which must come from external hydrodynamic calculations. A general kinetic equation representing the deterministic evolution of the joint distribution function for the cloud properties—position, velocity, size, and mass—is presented. The generalized coalescence equation is a moment form of this kinetic equation. A few comparisons of simulation results with known analytic solutions of restricted forms of the kinetic equation are made. A number of simplified problems involving pure coalescence with no ambient gas or external forces are then simulated in order to investigate the dependence of the final cloud mass spectrum on the adopted initial mass distribution, coalescence cross section, and initial velocity distribution. (118 refs.)

78805 The Jeans problem for a thin galaxy in steady state. R. Whitley (Univ. of California, Irvine, CA, USA).

J. Astrophys. & Astron. (India), vol.3, no.2, p.111-23 (June 1982). [received: June 1983]

Given the potential, the equation of continuity and Poisson's equation are solved for the variation perpendicular to the Galactic plane for a thin galaxy in a steady state. Simple expressions are obtained for the joint density function for the mass density and velocity, and for the distribution function for the velocity and its moments. These results are applied using a potential suggested by Woolley and Stewart (1967) and Whitley (1977), which is Camm's (1950) potential due to an isothermal gas stratified in parallel layers, plus the potential due to the galactic centre. A formula, valid under conditions more general than usual, is found for the total mass density in the neighbourhood of the Sun. (18 refs.)

78806 The massive neutrino and clustering phenomena in the Universe. Lu Tan, Zhu Peichen (Dept. of Astron., Nanjing Univ., Nanjing, China).

Kexue Tongbao [Foreign Lang. Ed.] (China), vol.28, no.1, p.63-8 (Jan. 1983). [received: June 1983]

The formation mechanisms of galaxies and clusters of galaxies are studied without the dust approximation, and the effect of the speed of sound is discussed. (9 refs.)

78807 Circumvention of Parker's bound on galactic magnetic monopoles. D.A. Dicus (Center for Particle Theory, Univ. of Texas, Austin, TX, USA), V.L. Teplitz.

Nature (GB), vol.303, no.5916, p.408-9 (2 June 1983).

There is a possibility that a magnetic monopole has been observed by Cabrera (1982). The monopole density implied by the observation appears to violate bounds on the density of such particles derived from the total mass density of the Universe and from the existence of galactic magnetic fields. The authors show that the observation is not inconsistent with these bounds if the monopoles and antimonopoles are bound into positronium like states with principal quantum n high enough so that the Earth's magnetic field will break them apart, but small enough so that the weaker galactic magnetic field will not. The authors determine a range of values for n and show that lifetimes for such bound states are longer than the current age of the Universe. (16 refs.)

78808 Gravitational waves. B. Muchotrzeb (Centrum Astron. im. M. Kopernika, Warszawa, Poland).

Postępy Astron. (Poland), vol.30, no.3-4, p.293-305 (July-Dec. 1982). In Polish. [received: April 1983]

Discusses the theoretical background of the phenomenon of gravitational waves. Simplifications are introduced to avoid applying the full general relativity formalism. (no refs.)

78809 Collisional vibrational quenching of $O_2^+(v)$ and other molecular ions in planetary atmospheres. B. Bohringer, M. Durup-Ferguson, E.E. Ferguson, D.W. Fahey (Aeronomy Lab., NOAA, Boulder, CO, USA).

Planet. & Space Sci. (GB), vol.31, no.4, p.483-7 (April 1983).

New experimental techniques have yielded several thermal energy vibrational quenching rate constants for $O_2^+(v)$. Rates for quenching of $O_2^+(v=1)$ by O_2 , N_2 , Ar, CO_2 , H_2 , and CH_4 are 3(-10), 2(-12), 1(-12), 1(-10), 2.5(-12), and 6(-10) $cm^3 s^{-1}$ at 300K. The quenching is somewhat faster for $O_2^+(v=2)$. The triatomic ions CO_3^+ , NO_2^+ , N_2O^+ , SO_2^+ , and H_2O^+ are all vibrationally deactivated with an efficiency greater than 10^{-3} in Ar or Ne collisions. A theoretical rationalisation of the experimental results leads to the prediction that vibrational quenching in planetary atmospheres will generally be efficient, $k > 1(-12) cm^3 s^{-1}$ for almost all ion and neutral gas pairs. (19 refs.)

78810 Magneto-atmospheric waves. J.H. Thomas (Dept. of Mech. Engng., Univ. of Rochester, Rochester, NY, USA).

In book: *Annual review of fluid mechanics. Vol.15*, M. Van Dyke, J.V. Wehausen, J.L. Lumley [Ed.], p.321-43. Palo Alto, CA, USA: Annual Reviews (1983), 534 pp. [0 8243 0715 1]

Magneto-atmospheric waves, or magneto-acoustic-gravity waves as they are also known, occur in a compressible, stratified, electrically conducting atmosphere under gravity, permeated by a magnetic field. These waves are supported by the combined restoring forces due to compression, buoyancy, and distortion of the magnetic field. They may be thought of as acoustic-gravity waves modified by the magnetic field or as magneto-acoustic waves modified by the stratification and buoyancy. The author considers the cases where all three restoring forces contribute to the wave motion. (66 refs.)

78811 Gamma-ray astronomy. R. Ramaty (Lab. for High-Energy Astrophys., NASA/Goddard Space Flight Center, Greenbelt, MD, USA), R.E. Linfenfelter.

In book: *Annual review of nuclear and particle science. Vol.32*, J.D. Jackson, H.E. Gove, R.F. Schwitters [Ed.], p.235-69. Palo Alto, CA, USA: Annual Reviews (1982), 595 pp. [0 8243 1532 4]

The authors describe gamma-ray observations from the solar system, from rapid nonsolar transients, from quasi-steady galactic sources and from extragalactic sites. They consider the most reliable and statistically significant observations; gamma-ray observations, in some cases, are still limited by counting statistics that can lead to questionable results. They particularly emphasize the physical processes responsible for astrophysical gamma-ray production. These involve processes of atomic physics (positronium formation and annihilation), of low-energy nuclear physics (deexcitation lines), of medium-

energy particle physics (π^0 meson production), of electromagnetism and magnetohydrodynamics (electron-positron pair production, confinement, and annihilation), as well as the more exotic processes in and around neutron stars, close to black holes, and possibly even in the early universe. (226 refs.)

78812 Dyon black hole in the Tomimatsu-Sato-Yamazaki space-time. M.Kasuya (Inst. for Nuclear Study, Univ. of Tokyo, Tokyo, Japan). Gauge Theory and Gravitation. Proceedings of the International Symposium, Nara, Japan, 20-24 Aug. 1982 (Berlin, Germany: Springer-Verlag 1983), p.41-4.

The symmetry between electric and magnetic charge which is inherent in Maxwell's equations does not seem to be realized in nature. Dirac pointed out, however, that quantum mechanics does not preclude the existence of magnetic monopoles. The author presents an exact stationary rotating dyon solution in the Tomimatsu-Sato-Yamazaki space-time. (13 refs.)

95.55 ASTRONOMICAL INSTRUMENTS

78813 The Clark Lake Teepee-Tee telescope. W.C.Erickson, M.J.Mahoney, K.Erb (Clark Lake Radio Obs., Univ. of Maryland, College Park, MD, USA). *Astrophys. J. Suppl. Ser. (USA)*, vol.50, no.3, p.403-19 (Nov. 1982). [received: May 1983]

A new, fully steerable, decametric array for radio astronomy has been built at the Clark Lake Radio Observatory near Borrego Springs, California. This array is a "T" of 720 conical spiral antennas (teepee-shaped antennas), 3.0 km by 1.8 km. It is capable of operating between 15 and 125 MHz but has best sensitivity in the 25 to 75 MHz range. Both its operating frequency and beam position are adjustable in ~ 1 ms. A 1024 channel digital correlator has been built and attached to the array. This permits the simultaneous measurement of the complex visibility functions on 512 interferometer baselines between various portions of the array. After Fourier transformation these visibility data yield a 32×32 resolution element picture of the area of sky under observation, with frequency-dependent angular resolution ranging from $20'$ to $2.7'$ and a sensitivity of 1 Jy per beam. The system is described, and some initial observations are presented. (5 refs.)

78814 A correlation interferometer for interplanetary scintillation observations. S.K.Alurkar, R.V.Bhonsle, R.Sharma, A.D.Bobra, Sohan Lal, N.S.Nirman, P.Venat, G.Sethia (Phys. Res. Lab., Ahmedabad, India). *J. Inst. Electron. & Telecommun. Eng. (India)*, vol.28, no.11, p.577-82 (Nov. 1982). [received: April 1983]

A correlation interferometer of the phase-switching type operating at a frequency of 103 MHz, developed for interplanetary scintillation (IPS) observation, is described. Two outputs, sin and cos, of the correlation receiver give rapidly changing voltage fluctuations produced by a compact scintillating radio source. A scintillometer output, proportional to the square of the scintillating flux, enables measurement of scintillation index. More than 100 strong and weak scintillating sources have been observed. This is the first of the three IPS radio telescopes being developed in India for studying the interplanetary medium. (14 refs.)

78815 Parameters of the radio telescope RT-3. M.Szymczak, A.Kus, G.Gawronska (Katedra Radioastron., Uniwersytet Mikołaja Kopernika, Toruń, Poland). *Postępy Astron. (Poland)*, vol.30, no.3-4, p.307-14 (July-Dec. 1982). In Polish. [received: April 1983]

Presents technical parameters of the 15-meter radio telescope and electrical characteristics. Special attention is paid to the pointing calibration. The antenna pattern, effective aperture and sensitivity are given. (18 refs.)

(inc. clocks, frequency standards)

78816 The Gallium Solar Neutrino Detector. W.Hampel (Max-Planck-Inst. für Kernphys., Heidelberg, Germany), R.Davis, Jr., B.T.Cleveland, G.Friedlander, S.Katcoff, L.P.Remser, J.K.Rowley, J.Weneser, T.Kirsten, W.Hampel, G.Heusser, M.Hubner, J.Kiko, E.Pernicka, R.Schlotz, R.Wunderlich, I.Dostrovsky, J.N.Bahcall, K.Lande, R.I.Steinberg. *AIP Conf. Proc. (USA)*, no.96, p.88-95 (1982). [received: May 1983] (Workshop on Science Underground, Los Alamos, CA, USA, 1982).

The author presents the status of the Gallium Solar Neutrino Experiment. The scientific goals of the experiment and the general experimental approach are described with details of the chemical procedure, the counting technique and the influence of background effects. (12 refs.)

78817 The Fly's Eye. R.Cady, G.L.Cassiday, J.Elbert, E.Loh, Y.Mizumoto, P.Sokolsky, D.Steck, M.Ye (Univ. of Utah, Salt Lake City, UT, USA). *AIP Conf. Proc. (USA)*, no.96, p.191-202 (1982). [received: May 1983] (Workshop on Science Underground, Los Alamos, CA, USA, 1982).

The authors describe a high energy physics observatory, the Fly's Eye, designed to measure extensive air showers in the energy range 10^{17} - 10^{21} eV via atmospheric fluorescence. Preliminary results are presented for the following measurements: (1) the high energy cosmic ray spectrum at 10^{17} - 10^{19} eV, (2) the total proton cross section σ_{pp} , (3) limits on the extra-galactic neutrino flux at 10^{20} eV. (7 refs.)

78818 Detection of gravitational collapse. J.C.Wheeler, J.A.Wheeler (Univ. of Texas, Austin, TX, USA). *AIP Conf. Proc. (USA)*, no.96, p.214-24 (1982). [received: May 1983] (Workshop on Science Underground, Los Alamos, CA, USA, 1982).

At least one kind of supernova is expected to emit a large flux of neutrinos and gravitational radiation because of the collapse of a core to form a neutron star. Such collapse events may in addition occur in the absence of any optical display. The corresponding neutrino bursts can be detected via Cerenkov events in the same water used in proton decay experiments. Dedicated equipment is under construction to detect the gravitational radiation. Events throughout the Galaxy could be detectable, but are expected only at intervals exceeding a decade. Nevertheless, the next event could come tomorrow, so every attempt should be made to make the monitoring for such events routine. (16 refs.)

78819 Microcomputer applications in space-borne instruments. W.C.Gibson (Dept. of Space Sci., Southwest Res. Inst., San Antonio, TX, USA). *Adv. Space Res. (GB)*, vol.2, no.7, p.153-62 (1982).

The recent applications of microprocessors to space experiments at Southwest Research Institute are presented. Some of the lessons learned from these applications are discussed. (no refs.)

78820 Method of calculating the expected background luminance from the Moon for planning astronomical observations. S.I.Vereshchagin, S.A.Likhomanov. *Sov. J. Opt. Technol. (USA)*, vol.49, no.9, p.551-3 (Sept. 1982). Translation of: *Opt.-Mekh. Prom-st. (USSR)*, vol.49, no.9, p.15-17 (Sept. 1982).

A calculation method is described for the a priori estimation of the background luminance from the Moon in a given region of the sky, based on the results of a statistical analysis of experimental data. The method has been implemented in the form of a library of computer programs, which permits a rapid consideration of the astrolimatic conditions of an observation point and to simulate the background luminance distribution in a given region of the sky when preparing to carry out observations of different classes of astronomical objects. 95.75 TECHNIQUES OF OBSERVATION AND REDUCTION

78821 The ages of the disks of S0 galaxies. N.Caldwell (Yale Univ. Obs., New Haven, CT, USA).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.90-101 (1 May 1983). A photometric system using a broad-band color combined with a line strength index is employed to distinguish age differences from metallicity differences between the bulges and disks of S0 galaxies. A color difference independent of metallicity changes of about $\Delta(U-V)=0.10$ is found for the sample of galaxies observed. Several S0 galaxies have absorption line strengths that indicate the disks are as metal rich as the most luminous elliptical galaxies. It is concluded that the disks of S0 galaxies are probably younger than the bulges, but the distinction between a younger turnoff and residual star formation cannot be made. (45 refs.)

78822 The brightest stars as extragalactic distance indicators. R.M.Humphreys (Univ. of Minnesota, Minneapolis, MN, USA). *Astrophys. J. (USA)*, vol.269, no.2, pt.1, p.335-51 (15 June 1983).

The luminosities of the brightest blue and red supergiants are calibrated by spectra and photometry of such stars in six Local Group galaxies. The visually brightest blue supergiants are all A type supergiants. Their luminosities depend strongly on the luminosity of the parent galaxy. The same relationship also occurs for the most luminous (bolometric) stars in the galaxies. There is a tight upper limit to the visual luminosities of the M supergiants at $M_{\text{bol}} = -8.0 \pm 0.2$ mag in spiral and irregular type galaxies covering nearly 6 mag of galactic luminosity from $M_{\text{bol}} = -20.5$ to -14.8 mag. The brightest M supergiant in each galaxy averages $M_{\text{bol}}(1) = -8.1 \pm 0.06$ mag with a σ of 0.14 mag, and the first three brightest M star luminosities in each of these six galaxies average $M_{\text{bol}}(3) = -7.9 \pm 0.07$ mag with a σ of 0.18 mag. The brightest M supergiants should be excellent extragalactic distance indicators for a wide range of galaxy types and luminosities. (45 refs.)

78823 A revised and extended calibration for the Spinrad-Taylor scanner system. B.J.Taylor (Dept. of Phys. & Astron., ESC, Brigham Young Univ., Provo, UT, USA).

Astrophys. J. Suppl. Ser. (USA), vol.50, no.3, p.391-401 (Nov. 1982). [received: May 1983]

New spectrophotometric data are presented for the standards of the Spinrad-Taylor scanner photometric system. The new data are in the 4040-6180 Å wavelength range and are used to construct a calibration of Spinrad-Taylor data to absolute units in this range. In addition, a previously published calibration for $\lambda > 6100$ Å is revised and extended through use of data in the literature. The calibrations—fused into a single whole—and the Spinrad-Taylor data themselves are tested for systematic error, partly through use of further new spectrophotometry at $\lambda > 6100$ Å; those tests which can currently be made yield generally satisfactory results. (39 refs.)

78824 Computational astrophysics on the array processor. R.T.Farouki, S.L.Shapiro, S.A.Teukolsky (Center for Radiophys. & Space Res., Cornell Univ., Ithaca, NY, USA).

Computer (USA), vol.16, no.6, p.73-83 (June 1983).

Modeling the dynamics of the universe is no small-scale problem and usually requires costly, off-site mainframes. Astrophysicists at Cornell, however, have found an economical, in-house alternative. Soon after an early model of the floating point systems AP-1901, array processor arrived at Cornell in 1978, theoretical astrophysicists and researchers joined physical scientists at the university who, together with Cornell Computer Services, were planning to finance and use the AP for large-scale scientific computing. They needed a means to tackle several large-scale, nonlinear problems in computational astrophysics and general relativity and had a rather limited computing budget to work with. They have used the AP to solve diverse problems in theoretical astrophysics and general relativity—problems that encompass many different physical regimes and, naturally, require a variety of solutions. The problems examined thus far deal either with the dynamical structure and evolution of self-gravitating, large N -body systems or with the spherical collapse of stars to black holes. These experiences are related. (33 refs.)

78825 The effectiveness of astronomical speckle transfer function reweighting algorithms. R.Barakat, P.Nisenson (Harvard Univ. Cambridge, MA, USA).

Opt. Commun. (Netherlands), vol.45, no.5, p.311-16 (1 May 1983).

Two methods for reweighting the astronomical speckle transfer function are compared using a combination of analysis and numerical computation. One method, long exposure subtraction is shown to perform well only for very short wavefront correlation lengths (shorter than the correlation length expected from a real atmosphere). The other method, reference star division is demonstrated to be effective and accurate, even when the wavefront statistics for the reference star data are substantially changed from the object data statistics. An experimental result using real telescope data is included which substantiates the analysis. (10 refs.)

78826 Research note: 13-color photometry, San Pedro Martir, 1973-79. W.J.Schuster (Inst. de Astron., Univ. Nacional Autonoma de Mexico, Mexico City, Mexico).

Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.3, p.149-60 (July 1982). [received: April 1983]

Atmospheric extinction data, probable errors of observation, standard star lists, observing procedures, reduction equations, and other miscellaneous data are given and discussed for 225 nights of 13-color photometry observed at the San Pedro Martir Observatory in Baja California. In addition a partial bibliography for the 13-color and Borgman photometric systems and for the uses of such intermediate-band photometry is presented. (49 refs.)

78827 A simple method of photographic photometry data reduction. J.M.Garcia-Pelayo, E.J.Alfaro (Inst. de Astrofísica de Andalucía, Granada, Spain).

Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.3, p.167-72 (July 1982). [received: April 1983]

Presents a variant of the standard methods in photographic photometry data reduction. The compact and fast least squares fitting with orthogonal polynomials has been combined with the analysis of variance, in order to obtain calibration curves corrected for magnitude and color effects. An example of application to four R plates (Becker's-RGL system) is also included. (10 refs.)

96.00 SOLAR SYSTEM

96.10 GENERAL, SOLAR NEBULA, AND COSMOGONY

- 78829 Extinct radioactivities: a three-phase mixing model. D.D. Clayton (Dept. of Space Phys. & Astron., Rice University, Houston, TX, USA), *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.381-4 (1 May 1983).
- A new class of models is advanced for interpreting the relationship of radioactive abundances in the early solar system to their average concentration in the interstellar medium. The model assumes that fresh radioactivities are ejected from supernovae into the hot interstellar medium, and that the time scales for changes of phase into molecular clouds determine how much survives for solar system formation. A more realistic and physically motivated understanding of the low observed concentrations of ^{129}I , ^{244}Pu , and ^{107}Pd may result. (18 refs.)
- 78830 On the stability of the Solar System. S.Kasperczuk (Zaklad Fizyki Politech. Swietokrzyskiej, Kielcach, Poland), *Postepy Astron. (Poland)*, vol.30, no.3-4, p.259-68 (July-Dec. 1982). In Polish. [received: April 1983]
- The problem of Solar System stability defined by Laplace and Lagrange in the second half of the 18th century, in celestial mechanics appears as Lagrange's theorem. The author presents data concerning Solar System stability. (22 refs.)

96.20 MOON

- 78831 Seismic velocity structure of the lunar mantle. Y. Nakamura (Inst. for Geophys., Univ. of Texas, Galveston, TX, USA), *J. Geophys. Res. (USA)*, vol.88, no.B1, p.677-86 (10 Jan. 1983). [received: May 1983]
- The recently completed set of seismic arrival times from the Apollo lunar seismic network have been inverted to estimate the average seismic velocities in three sections of the lunar mantle: two for the upper mantle and one for the middle mantle. The method used is a variation of the linearized least squares inversion where the inversion is accomplished in steps. The higher velocities of the middle mantle may suggest initial melting of the Moon down to at least 1000-km depth. (23 refs.)

96.30 PLANETS AND SATELLITES

(exc. the Moon; for celestial mechanics, see 95.10; for Earth as an astronomical body, see 91. Geophysics)

- 78832 The role of dissipation in shepherding of ring particles. R.Greenberg (Planetary Sci. Inst., Tucson, AZ, USA), *Icarus (USA)*, vol.53, no.2, p.207-18 (Feb. 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).
- In the absence of any damping mechanism, a shepherd satellite would force oscillations in the motion of a ring particle (relative to circular motion) that are symmetrical with respect to the encounter geometry. No net torque would be exerted by the satellite on the rings. Only in the presence of some damping mechanism can a particle's response lag so as to provide the asymmetry that permits a torque. The standard formula for the confining torque exerted by a shepherd satellite seems to be independent of damping. Moreover, many heuristic derivations of the formula tend to obscure the role of damping. (9 refs.)
- 78833 The dynamic tensile strength of ice and ice-silicate mixtures. M.A. Lange, T.J. Ahrens (Seismological Lab., California Inst. of Technol., Pasadena, CA, USA), *J. Geophys. Res. (USA)*, vol.88, no.B2, p.1197-208 (10 Feb. 1983).
- The dynamic tensile strength of ice and ice-silicate mixtures at strain rates of $\sim 10^4 \text{ s}^{-1}$ was determined. At these strain rates, ice has a tensile strength of $\sim 17 \text{ MPa}$, and ice-silicate mixtures with 5 and 30 wt.% sand content have strengths of ~ 20 and 22 MPa , respectively. These values lie significantly above tensile strengths of $\sim 1.6 \text{ MPa}$ for ice and of $\sim 5-6 \text{ MPa}$ for frozen silt, measured at strain rates of $\sim 10^{-2}$ to 10^0 s^{-1} , but markedly below values found for a variety of rocks at comparable strain rates. Results of the present experiments are used to derive parameters for continuum fracturing models in icy media, which are used to determine relations between tensile strength and strain rate, and to predict stress and damage histories as well as size frequency distributions for ice and ice-silicate fragments. (22 refs.)
- 78834 Anomalous bulk viscosity of two-phase fluids and implications for planetary interiors. D.J. Stevenson (Div. of Geological & Planetary Sci., California Inst. of Technol., Pasadena, CA, USA), *J. Geophys. Res. (USA)*, vol.88, no.B3, p.2445-55 (10 March 1983).
- A calculation is presented for the irreversible entropy production that accompanies the imposition of a pressure perturbation on a two-phase medium consisting of a dilute suspension of one phase in another (liquid) phase of significantly different composition. No metastability is allowed, and the relaxation process is then dominated by the finite diffusivity of solute. The fluid medium behaves as though it has a very large bulk viscosity (typical value $\sim 10^{12} \text{ P}$ in the low-frequency limit). The minimum quality factor Q for acoustic or tidal pressure oscillations is found to be typically $\sim 10^2-10^3$. The model is applied to helium rain clouds in the deep interiors of giant planets

and is found to be capable in principle of providing a tidal $Q \sim 10^5$, needed to explain the volcanism of Io and resurfacing of Enceladus. The model is also applied to the Earth's outer core and found to be marginally capable of explaining the attenuation of radial modes and potentially capable of providing significant attenuation of Earth tides. (40 refs.)

78835 Crater ejecta scaling laws: fundamental forms based on dimensional analysis. K.R.Housen, R.M.Schmidt (Shock Phys. & Appl. Mech., Boeing Aerospace Co., Seattle, WA, USA), K.A.Holsapple. *J. Geophys. Res. (USA)*, vol.88, no.B3, p.2485-99 (10 March 1983).

A model of crater ejecta is constructed using dimensional analysis and a recently developed theory of energy and momentum coupling in cratering events. General relations are derived that provide a rationale for scaling laboratory measurements of ejecta to larger events. Specific expressions are presented for ejection velocities and ejecta blanket profiles in two limiting regimes of crater formation: the so-called gravity and strength regimes. In the gravity regime, ejecta velocities at geometrically similar launch points within craters vary as the square root of the product of crater radius and gravity. In the strength regime, ejecta velocities are independent of crater size. (39 refs.)

78836 Planetary magnetic fields. D.J.Stevenson (Div. of Geological & Planetary Sci., California Inst. of Technol., Pasadena, CA, USA). *Rep. Prog. Phys. (GB)*, vol.46, no.5, p.555-620 (May 1983).

As a consequence of the smallness of the electronic fine structure constant, the characteristic time scale for the free diffusive decay of a magnetic field in a planetary core is much less than the age of the Solar System, but the characteristic time scale for thermal diffusion is greater than the age of the Solar System. Consequently, primordial fields and permanent magnetism are small and the only means of providing a substantial planetary magnetic field is the dynamo process. This requires a large region which is fluid, electrically conducting and maintained in a non-uniform motion that includes a substantial RMS vertical component. The attributes of fluidity and conductivity are readily provided in the deep interiors of all planets and most satellites, either in the form of an Fe alloy with a low eutectic temperature (e.g. Fe-S-O in terrestrial bodies and satellites) or by the occupation of conduction states in fluid hydrogen or 'ice' ($H_2O-NH_3-CH_4$) in giant planets. It is argued that planetary dynamos are almost certainly maintained by convection (compositional and/or thermal). (184 refs.)

96.30D Mercury

78837 Tectonic evolution of Mercury: comparison with the Moon. P.G.Thomas, P.Masson (Lab. de Geologie Dynamique Interne, Univ. Paris-Sud, Orsay, France).

Ann. Geophys. (France), vol.1, no.1, p.53-8 (Jan.-Feb. 1983). With regard to the Earth or to Mars, the Moon and Mercury look like tectonically planetary bodies, and the prominent morphologies of these two planets are due to impact and volcanic processes. Despite these morphologies, several types of tectonic activities may be shown. Statistical studies of lineaments direction indicate that Mercury, as well as the Moon, have a planet wide lineament pattern, known as a 'grid'. Statistical studies of Mercury scarps and the Moon grabens indicate an interaction between planetary lithospheric evolution and large impact basins. Detailed studies of the largest basins indicate specific tectonic motions directly related to impacts. These three tectonic types are compared on each planet. (26 refs.)

96.30E Venus

78838 Venus gravity anomalies and their correlations with topography. W.L.Sjogren, B.G.Bills, P.W.Birkeland, P.B.Esposito, A.R.Konopliv, N.A.Mottinger, S.J.Ritke (Jet Propulsion Lab., Pasadena, CA, USA), R.J.Phillips.

J. Geophys. Res. (USA), vol.88, no.B2, p.1119-28 (10 Feb. 1983). This report provides a summary of the high-resolution gravity data obtained from the Pioneer Venus Orbiter radio tracking data. Gravity maps, covering a 70° latitude band through 360° of longitude, are displayed as line-of-sight and vertical gravity. Topography converted to gravity and Bouguer gravity maps are also shown in both systems. Topography to gravity ratios are made over several regions of the planet. There are markedly different ratios for the Aphrodite area as compared to the Beta and Atla areas. (10 refs.)

96.30G Mars

78839 The stability of ground ice in the equatorial region of Mars. S.M.Clifford (Dept. of Phys. & Astron., Univ. of Massachusetts, Amherst, MA, USA), D.Hillel.

J. Geophys. Res. (USA), vol.88, no.B3, p.2456-74 (10 March 1983). Consideration of the partial pressure of H_2O in the Martian atmosphere and the range of mean annual temperatures at the Martian surface suggests that the occurrence of ground ice in equilibrium with the atmosphere is restricted to latitudes poleward of $\pm 40^\circ$. However, there is a growing body of morphologic evidence that indicates that substantial quantities of ground ice may have been present in the equatorial regolith throughout Martian geologic time. The accepted explanation for this apparent contradiction has been that the H_2O found near the equator is a relic, emplaced very early in Martian geologic history and under substantially different climatic conditions. It is generally believed that this fossil ground ice layer has been preserved to the present day by the diffusion-limiting properties of a relatively shallow layer (≤ 10 m) of fine-grained regolith. To evaluate this hypothesis, the lifetime of a 200-m layer of ground ice, buried below 100 m of ice-free regolith, has been examined for the latitudes between $\pm 30^\circ$ on Mars. Twelve model pore size distributions, representative of silt and clay-type soils found on Earth, were selected to simulate the pore structure of the Martian regolith. The parallel pore model of gaseous diffusion was then used to calculate the flux of escaping H_2O molecules from the buried ground ice layer. Important factors affecting the stability of equatorial ground ice appear to be (1) soil structure, (2) the magnitude of the geothermal gradient, and (3) the climatic desorption of CO_2 from the regolith. We conclude that while the conditions necessary for the long-term survival of ground ice may exist in isolated regions within the equatorial regolith, on the global scale it appears unlikely that a fossil ground ice layer has been preserved throughout Martian geologic history. If massive ground ice does presently exist in the equatorial regolith, then its presence may imply the existence of some continuous or periodic process of replenishment. (130 refs.)

78840 Interpretation of whole-disk photometry of Phobos and Deimos. K.D.Pang, J.W.Rhoads, G.A.Hanover (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA), K.Lumme, E.Bowell.

J. Geophys. Res. (USA), vol.88, no.B3, p.2475-84 (10 March 1983). The phase curves (whole-disk brightness vs. solar phase angle) of the Martian satellites were compiled out to 125° phase angle from ground-based and spacecraft photometric observations. The data were modeled with the Lumme-Bowell theory. Accurate phase integrals, zero-phase geometric albedos and Bond albedos were obtained from the best fit theoretical curves. The microstructural and particulate surface properties of Phobos differ little from those of Deimos. The satellites' very similar whole-body densities and geochemical and microphysical makeup suggest a common origin. However, having spent a considerable portion of their lifetimes in proximity to Mars probably did modify their surface characteristics. The value of the surface roughness, the debris mantle on Deimos and the grooves on Phobos are probably evidence of such modifications. (41 refs.)

Transits of Earth as seen from Mars See Entry 78797

96.30H Asteroids

78841 UBV photometry of the minor planets 86 Semele, 521 Brixia, 53 Kalypso and 113 Amalthea. J.Surdej, A.Surdej, B.Louis (Inst. d'Astrophys. Univ. de Liege, Ougree-Liege, Belgium).

Astron. & Astrophys. Suppl. Ser. (France), vol.52, no.2, p.203-11 (May 1983).

Asteroids 86 Semele, 521 Brixia and 53 Kalypso, 113 Amalthea were observed photometrically during the 1980 and 1981 oppositions, respectively. Synodic rotation periods, color indices and light variations are determined. The $B-V$ and $U-B$ color indices of these four minor planets do not present any variation exceeding the mean scatter over the observed rotation cycles. (10 refs.)

78842 Asteroid occultations: a 1981 status report. P.D.Maley (Ford Aerospace & Communications Corp., NASA Johnson Space Center, Houston, TX, USA).

Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.3, p.213-16 (July 1982). [received: April 1983]

A summation is presented of the historical observations, methods of prediction, and results of the known Earth-based sightings of occultations of stars by minor planets through the end of 1981. Techniques are outlined to encourage uniformity in site positioning, data recording, and observer training. (27 refs.)

96.30K Jupiter

78843 Observed departure of the IO plasma torus from rigid corotation with Jupiter. R.A.Brown (Space Telescope Sci. Inst., Baltimore, MD, USA).

Astrophys. J. Lett. Ed. (USA), vol.268, no.1, pt.2, p.L47-50 (1 May 1983). A study of [S II] red doublet spectra indicates that the Io plasma torus at $5.9 R_J$ does not corotate rigidly with Jupiter. The lag is found to be $6\% \pm 4\%$, where the variability range, not the uncertainty, is indicated. Comparison with existing models indicates the lag may be due primarily to ion creation in the Io torus. (16 refs.)

78844 Jupiter's satellites J VI and J VII. Ephemerides for the years 1981 to 1990. P.Rocher (Service de Mecanique Celeste du Bureau des Longitudes, Paris, France).

Astron. & Astrophys. Suppl. Ser. (France), vol.52, no.2, p.333-72 (May 1983).

The proposed ephemerides come from a numerical integration of G.B.S. type (Gragg-Bulirsch-Stoer). The numerical constants of integration are given. The observational data are analogous to those used by Bordoovystina and Bykova (1978). Mean values and standard deviations in the O-C s are listed. The published quantities are equatorial astrometric coordinates: right ascension, declination and true distance Jupiter-satellite. (2 refs.)

Anomalous bulk viscosity of two-phase fluids and implications for planetary interiors See Entry 78834

96.30M Saturn

78845 J.E. Keeler's discovery of a gap in the outer part of the A ring. D.E.Osterbrock (Lick Obs., Board of Studies in Astron. & Astrophys., Univ. of California, Santa Cruz, CA, USA), D.P.Cruikshank.

Icarus (USA), vol.53, no.2, p.165-73 (Feb. 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).

In early January 1888, James E. Keeler was one of the first astronomers to work with the very new Lick Observatory 36-in refractor. On January 7 while observing Saturn visually on a night of very fine seeing, he discovered a narrow, dark 'division' in the outer part of the A-ring. Neither Keeler nor any of the other Lick observers saw this gap again until over a year later on March 2, 1889. On that occasion not only Keeler, but also E.S. Holden, J.M. Schaeberle, and E.E. Barnard, all observed 'Mr. Keeler's division', as Barnard called it. The outer edge of the Encke division is where Keeler placed his gap, although he did not see the low-contrast structure in the Encke division. The images obtained from the Pioneer and Voyager space probes confirm the narrow Keeler feature as a true gap in the outer part of the A-ring. (24 refs.)

78846 Theoretical interpretation of the ground-based photometry of Saturn's B ring. K.Lumme, W.M.Irvine (Dept. of Phys. & Astron., Univ. of Massachusetts, Amherst, MA, USA), L.W.Esposito.

Icarus (USA), vol.53, no.2, p.174-84 (Feb. 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).

New photographic photometry at small tilt angles during the 1979 and 1981 apparitions is combined with earlier data to yield several physical parameters for Saturn's B-ring in red and blue colours. Phase curves are obtained for a mean tilt angle $B \approx 6^\circ$. The value of the volume density is discussed. The results and the derived amount of multiple scattering as a function of tilt angle constrain the particle phase function in the red to be moderately back-scattering. No indication was found that the particle photometric properties might depend on the vertical distance from the central plane. The results show that the ground-based photometry is entirely consistent with the classical, many-particle-thick ring model. (24 refs.)

78847 Bending waves in Saturn's rings. F.H.Shu, J.N.Cuzzi, J.J.Lissauer (Astron. Dept., Univ. of California, Berkeley, CA, USA).

Icarus (USA), vol.53, no.2, p.185-206 (Feb. 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).

Investigates certain brightness variations seen in Saturn's A-ring. The authors find them to be due to vertical corrugations of the local ring plane caused by a spiral bending wave. This wave is resonantly excited by Mimas and propagates

ates inward via the collective gravity of the ring particles. Smith et al. (1981) had previously associated vertical relief with this feature due to its observed azimuthal variations and its proximity to an inclination resonance with Mimas. The authors develop the theory of forced bending waves, some aspects of which have been treated in the galactic context by Hunter and Toomre (1969) and by Bertin and Mark (1980). The presence of these bending waves may resolve the conflict between ground-based estimates of 1-2 km for the global ring thickness, e.g. Brahic and Sicardy (1981) and Voyager stellar occultation measurements of <200 m for the local ring thickness (Lane et al., 1982; Marouf and Tyler, 1982). (23 refs.)

78848 A model for the formation of spokes in Saturn's ring. C.K.Goertz, G.Morfill (Max-Planck-Inst. für Aeronomie, Katlenburg-Lindau, Germany). *Icarus (USA)*, vol.53, no.2, p.219-29 (Feb. 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982). Suggests that spokes consist of charged micron-sized dust particles elevated from the rings by radially moving dense plasma columns created by meteoroid impacts on the ring. Dense plasma causes electrostatic wall-sheaths at the ring and charging of the ring with electric fields strong enough to overcome the gravitational force on small dust particles. Under 'ordinary' conditions only very few dust particles will be elevated as the probability of a dust particle having at least one excess electronic charge is very low. Dense plasma raises this probability significantly. The radial motion of the plasma column is due to an azimuthal polarisation electric field built up by the relative motion between the corotating plasma and the negatively charged dust particles which move with a Keplerian speed. (26 refs.)

78849 On the evolution of Saturn's 'spokes': theory. G.E.Morfill (Max-Planck-Inst. für Extraterrestrische Phys., Garching, Germany), F.Grun, C.K.Goertz, T.V.Johnson. *Icarus (USA)*, vol.53, no.2, p.230-5 (Feb. 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982). Starting with the assumption that negatively charged micron-sized dust grains may be elevated above Saturn's ring plane by plasma interactions, the subsequent evolution of the system is discussed. The discharge of the fine dust by solar UV radiation produces a cloud of electrons which moves adiabatically in Saturn's dipolar magnetic field. The electron cloud is absorbed by the ring after one bounce, alters the local ring potential significantly, and reduces the local Debye length. As a result, more micron-sized dust particles may be elevated above the ring plane and the spoke grows. This process continues until the electron cloud has dissipated. (11 refs.)

78850 Micron-sized particles detected near Saturn by the Voyager plasma wave instrument. D.A.Gurnett, E.Grun, D.Gallagher, W.S.Kurth, F.L.Scarf (Dept. of Phys. & Astron., Univ. of Iowa, Iowa City, IA, USA). *Icarus (USA)*, vol.53, no.2, p.236-54 (Feb. 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982). During the Voyager 2 Saturn encounter the plasma wave instrument detected a region of intense impulsive noise centred on the ring plane at a distance of 2.88 Saturn radii, slightly outside of the G-ring. The noise has been attributed to small micron-sized particles hitting the spacecraft. Investigation of various coupling mechanisms suggested that the noise was produced by impact ionisation of particles striking the spacecraft body, thereby releasing a cloud of charged particles, some of which were collected by the plasma wave antenna. A method was developed to determine the mass and size distribution of the particles from the RMS voltage of the induced noise and the impulse rate. The results obtained show that the mass distribution varies as m^{-3} , and that most of the particles detected had radii in the range from 0.3 to 3 μm . The effective north-south thickness of the particle distribution is 106 km. (19 refs.)

78851 A search for Saturn electrostatic discharges in the Voyager plasma wave data. W.S.Kurth, D.A.Gurnett, F.L.Scarf (Dept. of Phys. & Astron., Univ. of Iowa, Iowa City, IA, USA). *Icarus (USA)*, vol.53, no.2, p.255-61 (Feb. 1983). Voyager plasma wave data are searched for evidence of Saturn electrostatic discharges which have previously been reported by the planetary radio astronomy team following the Voyager 1 and 2 encounters with Saturn. On the basis of the radio astronomy observations, the discharges should have been observable by the plasma wave experiment on Voyager; however, there is no evidence in the plasma wave data for the phenomenon. The authors analyse the statistical significance and comment on the ramifications of this null result and entertain various explanations of the lack of plasma wave observations of electrostatic discharges, including the possibility that many events are of a much shorter duration than previously reported or that there could possibly be a nonlinear distortion in the radio astronomy receiver which could artificially broaden the spectrum of the discharges. (9 refs.)

78852 Albedo, internal heat flux, and energy balance of Saturn. R.A.Hanel, B.J.Conrath, V.G.Kunde, J.C.Pearl, J.A.Pirraglia (Lab. for Extraterrestrial Phys., NASA/Goddard Space Flight Center, Greenbelt, MD, USA). *Icarus (USA)*, vol.53, no.2, p.262-85 (Feb. 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982). Full-disk and high-resolution measurements recorded during the Voyager 1 flyby of Saturn by the radiometer of the infrared instrument, IRIS, indicate a geometric albedo which is lower than previous estimates. Combining this measurement with the Pioneer-derived phase integral yields a Bond albedo. Infrared spectra recorded at the same time by the Michelson interferometer, along with a model extrapolation to wavenumbers not covered by the instrument, yield an effective temperature. The rings of Saturn significantly affect both the short- and long-wavelength fluxes. From these measurements the internal heat flux and the energy balance are determined. (51 refs.)

78853 Thermal structure of Saturn from Voyager infrared measurements: implications for atmospheric dynamics. B.J.Conrath, J.A.Pirraglia (Lab. for Extraterrestrial Phys., Goddard Space Flight Center, Greenbelt, MD, USA). *Icarus (USA)*, vol.53, no.2, p.286-92 (Feb. 1983). Saturn atmospheric temperatures at the 150-mbar level retrieved from Voyager IRIS measurements indicate the presence of small-scale meridional gradients which are approximately symmetric with respect to the equator, but are superposed on a large-scale hemispheric thermal asymmetry. Under the assumption that the retrieved values at this atmospheric level represent kinetic temperatures on a constant pressure surface, it is suggested that the small-scale structure is produced by a meridional circulation associated with the dissipative decay of the zonal winds with height, while the hemispheric asymmetry represents a thermal response to the seasonally varying insolation. The small-scale gradients are correlated with zonal winds derived from Voyager images at mid and high latitudes through the thermal wind relation. (16 refs.)

78854 Thermal infrared constraints on ammonia ice particles as candidates for clouds in the atmosphere of Saturn. G.S.Orton (Jet Propulsion Lab., Earth & Space Sci. Div., California Inst. of Technol., Pasadena, CA, USA). *Icarus (USA)*, vol.53, no.2, p.293-300 (Feb. 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).

It is possible for large particles of NH_3 ice to explain two phenomena associated with observations of thermal infrared emission from the atmosphere of Saturn: (1) the depression of thermal brightness near the equator, which is coincident with a visibly bright zone-like region, and (2) some disagreements between infrared and radio occultation results. Particles of NH_3 ice can provide the requisite opacity to explain the contrast between the equatorial region and the brighter area near 15°S for Pioneer Saturn Infrared Radiometer $45\text{-}\mu\text{m}$ channel data. NH_3 ice particle clouds can also reconcile the $45\text{-}\mu\text{m}$ brightness of both regions (near the equator and near 15°S) with the mean temperature structure of the Voyager 2 radio occultation results. A cloud model with ice particles distributed in equal ratio with gas particles up to the 100-mbar pressure level best fits the equatorial data; a thinner cloud or one which does not extend higher than the 400-mbar limit of the convective region best matches data for the 15°S region. (29 refs.)

78855 Spatially resolved methane band photometry of Saturn. II. Cloud structure models at four latitudes. R.A.West (Dept. of Astro-Geophys., Univ. of Colorado, Boulder, CO, USA). *Icarus (USA)*, vol.53, no.2, p.301-9 (Feb. 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).

For pt.I see *ibid.*, vol.51, no.1, p.51-64 (1982). Spatially resolved measurements of Saturn's reflectivity in the 6190-, 7250-, and 8996-Å methane bands are analysed to determine cloud vertical structures in the Equatorial Zone, South Equatorial Belt, and North and South Temperate Regions near latitudes $\pm 30^\circ$. Radiative transfer models are computed for a simple two-parameter structure. The parameters are the methane column abundance in an aerosol-free layer at the top of the atmosphere, and the specific abundance of methane in a semi-infinite homogeneous gas and cloud mixture deep in the atmosphere. Some suggestions are proposed to explain differences between model parameters derived using different absorption bands. (18 refs.)

78856 Spectrophotometry of Saturn and its rings from 60 to 180 microns. G.Melnick, R.W.Russell, T.R.Gosnell, M.Harwit (Centre for Radiophys. & Space Res., Cornell Univ., Ithaca, NY, USA).

Icarus (USA), vol.53, no.2, p.310-18 (Feb. 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982). Observes Saturn at far-infrared and submillimeter wavelengths during the Earth's March 1980 passage through the plane of Saturn's rings. Comparison with earlier spectroscopic observations by Ward (1977), obtained at a time when the tilt angle of the rings was 21.8° , permits separation of the disk and ring contributions to the flux observed in this wavelength range. The observed emission of the disk between 60 and 180 μm corresponds to a brightness temperature of $104 \pm 2\text{K}$, and the brightness temperature of the ring drops approximately 20K between 60 and 80 μm . The data, in conjunction with the data obtained by other observers between 1 μm and 1 mm, permit the authors to derive an improved estimate for the total Saturnian surface brightness effective temperature ratio of radiated to incident power and intrinsic luminosity. (37 refs.)

78857 The evolution of Enceladus. S.W.Squyres, R.T.Reynolds, P.M.Cassen (NASA Ames Res. Centre, Moffett Field, CA, USA), S.J.Peale. *Icarus (USA)*, vol.53, no.2, p.319-31 (Feb. 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).

Describes the tectonic features of Enceladus and presents a preliminary analysis of the relation between internal geophysical processes and the formation of these features. The authors conclude that H_2O or $\text{H}_2\text{O-NH}_3$ vulcanism was responsible for resurfacing portions of the satellite, and that global expansion played a role in the formation of grooves. It is clear that some heat source has been active for an extended period of Enceladus' history. Theoretical calculations suggest that tidal heating is the most likely possibility, but only if Enceladus' orbit has evolved markedly in the last few billion years. Evidence that the satellite is currently being significantly heated is discussed. (31 refs.)

78858 The control networks of Mimas and Enceladus. M.E.Davies, F.Y.Katayama (Rand Corp., Santa Monica, CA, USA).

Icarus (USA), vol.53, no.2, p.332-40 (Feb. 1983). Control networks for Mimas and Enceladus are computed using a bundle-type analytical triangulation program. The Mimas network encircles the satellite with 110 points measured on 32 Voyager 1 pictures. The adjustment contained 1356 observation equations and 316 normal equations, and gives a standard error of measurement of 13.43 μm . The Enceladus network does not completely encircle the satellite; it contains 71 points measured on 22 Voyager 2 pictures. The adjustment contains 994 observation equations and 208 normal equations, and gives a standard error of measurement of 19.19 μm . Many of the control points are identified on illustrations and by name and their coordinates are given in tables. The analytical triangulation program is used to solve for the mean radii and the three principal axes of best-fit ellipsoids. (9 refs.)

78859 Eight-colour photometry of Hyperion, Iapetus, and Phoebe. D.J.Tholen, B.Zellner (Lunar & Planetary Lab., Univ. of Arizona, Tucson, AZ, USA).

Icarus (USA), vol.53, no.2, p.341-7 (Feb. 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).

Eight-colour spectrophotometry was obtained of Phoebe, Hyperion, and the dark side of Iapetus. The V magnitudes and Voyager-derived diameters yield geometric albedos for Iapetus, Phoebe, and Hyperion. Hyperion and Iapetus have quite reddish spectra similar to each other and the spectra of D-type asteroids. Hyperion, however, has a much higher albedo than the dark side of Iapetus or any D-type asteroid measured to date. The mean spectrum of Phoebe is much flatter, with a broad absorption feature near 1 μm . Therefore the surface materials of Phoebe and the dark side of Iapetus are optically quite different, a result that constrains the possible modes of interaction between Phoebe and the other two satellites. (24 refs.)

78860 The atmosphere of Titan: an analysis of the Voyager 1 radio occultation measurements. G.F.Lindal, G.E.Wood, H.B.Hotz, D.N.Sweetnam (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA), V.R.Eshleman, G.L.Tyler.

Icarus (USA), vol.53, no.2, p.348-63 (Feb. 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982). Two coherently related radio signals transmitted from Voyager 1 at wavelengths of 13 cm (S-band) and 3.6 cm (X-band) were used to probe the equatorial atmosphere of Titan. The measurements were conducted during the occultation of the spacecraft by the satellite on November 12 1980. An analysis of the differential dispersive frequency measurements did not reveal any ionisation layers in the upper atmosphere of Titan. Abrupt signal changes observed at ingress and egress indicate a surface radius which leads to a mean density for the satellite. The non-dispersive data are used to derive profiles in height of the gas refractivity data, which extend from the surface

to about 200 km altitude, is interpreted. Arguments concerning the temperature lapse rates computed from the radio measurements appear to favour models in which methane forms at most a limited haze layer high in the troposphere. (28 refs.)

78861 Radiative equilibrium model of Titan's atmosphere. R.E.Samuelson (Lab. for Extraterrestrial Phys., NASA/Goddard Space Flight Centre, Greenbelt, MD, USA).

Icarus (USA), vol.53, no.2, p.364-87 (Feb. 1983). (Saturn Conference, Tucson, AZ, USA, 11-15 May 1982).

A simple global radiative equilibrium model is developed for Titan. It is restricted to the two-stream approximation, is vertically homogeneous in its scattering properties, and is spectrally divided into one thermal and two solar channels. A partially absorbing 'violet' channel is responsible for heating in the stratosphere, while a conservatively scattering 'red' channel permits heating at the surface. The spectrally integrated mass absorption coefficient at thermal wavelengths is approximately constant throughout the stratosphere and roughly linear with pressure in the troposphere. This in turn implies the presence of a uniformly mixed aerosol in the stratosphere, and suggests pressure-induced absorption by gaseous N_2 - CH_4 - H_2 in the troposphere. In addition there appear to be two regions of enhanced opacity near 30 and 500 mbar which may be due to C_2H_2 - C_2H_6 - C_3H_8 and CH_4 condensation clouds, respectively. (33 refs.)

78862 Voyager to Jupiter and Saturn: the journey of a lifetime. II. G.E.Hunt (Imperial Coll., London, England).

J. Br. Astron. Assoc. (GB), vol.93, no.3, p.105-10 (April 1983).

For pt.1 see *ibid.*, vol.93, no.2, p.62-9 (1983). Discusses the satellites of Jupiter and the rings. (2 refs.)

Saturn Conference See Entry 74211

The far-infrared spectrum of ice Ih in the range 8-25 cm^{-1} . Sound waves and difference bands, with application to Saturn's rings See Entry 77376

78863 Occultation of Hyd -22°58794 by Neptune on 1983 June 15. D.Mink.

I.A.U. Circ. (USA), no.3818, 1 pp. (1 June 1983).

Presents improved predictions for this event indicating that the centre of Neptune's shadow will pass near the Earth's south pole. Possible ring occultations are mentioned. (1 ref.)

78864 Tentative confirmation of an aurora on Uranus. J.Caldwell, R.Wagener, T.Owen (Dept. of Earth & Space Sci., State Univ. of New York, Stony Brook, NY, USA), M.Combes, T.Encrenaz.

Nature (GB), vol.303, no.5915, p.310-12 (26 May 1983).

Reports the detection of emission features due to molecular hydrogen, H_2 , near 1,600 Å. This detection is near the limit of the IUE sensitivity. If it is real, the detection of H_2 emission strongly supports the conclusion that Uranus has an aurora comparable in strength with those of the inner two giant planets, Jupiter and Saturn. The first published IUE spectra of the Saturn aurora are also presented. (7 refs.)

78865 The integral equation approach to the study of interplanetary dust.

J.Buitrago, R.Gomez, F.Sanchez (Inst. de Astrofisica de Canarias, Univ. de La Laguna, La Laguna, Canary Islands, Spain).

Planet. & Space Sci. (GB), vol.31, no.4, p.373-6 (April 1983).

Some considerations about the zodiacal light (ZL) brightness integral from the standpoint of the theory of integral equations are made. It is shown that for observation directions confined to a plane perpendicular to the ecliptic and passing through the Sun, the ZL brightness integral can be formally considered as a first kind integral equation of Volterra type (VIE). In a second step, this equation is transformed into a VIE of the second kind, from which, and under certain assumptions, the spatial distribution of dust out of the ecliptic is obtained. (13 refs.)

96.50G Comets

78866 Dynamic stabilization of hydromagnetic surface waves: applications to cometary plasma tails. B.Buti (Phys. Res. Lab., Ahmedabad, India).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.420-7 (1 May 1983).

Hydromagnetic waves, at the interface of two superposed magnetofluids, are studied in the presence of electrostatic coherent waves propagating parallel to the surface of discontinuity. Due to nonlinear interaction with the electrostatic waves, hydromagnetic waves, which may be unstable otherwise, can be stabilized. The model developed is applied to study the interaction of the solar wind with the cometary plasma tails. (10 refs.)

78867 High-resolution spectra of C_2 Swan bands from Comet West 1976 VI [sic]. D.L.Lambert (Dept. of Astron., Univ. of Texas, Austin, TX, USA), A.C.Danks.

Astrophys. J. (USA), vol.268, no.1, pt.1, p.428-46 (1 May 1983).

A 0.3 Å resolution spectrum of the $\Delta v = +1$ sequence in the C_2 Swan system from Comet West 1976 VI at a heliocentric distance $r_H = 0.78$ AU is found to correspond to a vibrational and rotational temperature of $T_{ex} = 3500 \pm 400$ K for the upper $d''\Pi_g$ state. If intercombination transitions are neglected, the predicted temperature for C_2 excited by fluorescence in sunlight is considerably hotter than the observed temperature. The triplet C_2 states may be cooled by intercombination transitions linking the triplet and singlet states. The electronic transition moment of the $d''\Pi_g - A''\Sigma_g^+$ transition is estimated. On high-resolution spectra of selected lines in the Swan 0-0 band, several $^{12}C^{13}C$ lines are identified. The 0-0 band is probably superior to the 1-0 $^{12}C^{13}C$ 4745 Å band head for $^{12}C/^{13}C$ ratio determinations. (47 refs.)

78868 Comet IRAS (1983f). J.Davies, K.S.Russell.

I.A.U. Circ. (USA), no.3814, 1 pp. (20 May 1983).

It is reported that the Infrared Astronomical Satellite has discovered a 17th-magnitude comet in Hydra. Two approximate positions are reported for the epoch 1983 May 13, and two semi-accurate positions for 1983 May 18. (no refs.)

78869 Comet IRAS (1983f). J.Davies, B.G.Marsden.

I.A.U. Circ. (USA), no.3815, 1 pp. (24 May 1983).

Reports additional observations with the IRAS on 1983 May 23, parabolic orbital elements and an ephemeris for the period 1983 February 15-July 5 at 10-day intervals. (no refs.)

78870 Periodic Comet Du Toit-Neujmin-Delporte (1983g). J.Gibson.

I.A.U. Circ. (USA), no.3816, 1 pp. (1 June 1983).

Reports the recovery on 1.2 m Palomar Schmidt plates, precise positions on 1983 May 20 and 21, a description of the objects appearance and the ephemeris correction. (1 ref.)

78871 Comet Sugano-Saigusa-Fujikawa (1983e). Y.Takatsuki, T.Seki, K.Suzuki, J.Gibson, E.Everhart, R.E.McCrosky, B.G.Marsden.

I.A.U. Circ. (USA), no.3816, 1 pp. (1 June 1983).

Reports precise positions for the period 1983 May 10-22 and presents parabolic orbital elements determined from 22 observations from 1983 May 9-21. (2 refs.)

78872 Comet IRAS-Araki-Alcock (1983d). G.Richter, W.Altenhoff, W.Batrla, W.Huchtmeier, J.Schmidt, P.Stumpff, M.Walmsley, R.Nolthenius, J.D.Drummond, V.F.de Assis Neto.

I.A.U. Circ. (USA), no.3817, 1 pp. (1 June 1983).

Reports a 1983 April 17 prediscovery position, 13 mm wavelength observations of a pointlike continuum source, NH_3 and H_2O line detections, brightness temperature determinations on May 11 and 12, visual observations of an occultation of SAO 98040 on May 12, a minor meteor shower, and total visual magnitude estimates for the period May 11-18. (2 refs.)

78873 Periodic Comet Tempel 2 (1982d). J.Bortle.

I.A.U. Circ. (USA), no.3817, 1 pp. (1 June 1983).

Reports total visual magnitude estimates for 1983 May 14 and 18.

78874 Comet IRAS (1983f). J.Gibson.

I.A.U. Circ. (USA), no.3818, 1 pp. (1 June 1983).

Presents precise positions for 1983 May 18 and 20 and an approximate position for May 31.

78875 Periodic Comet Kopff (1982k). J.E.Bortle, C.E.Spratt, J.D.Shanklin, J.-C.Merlin.

I.A.U. Circ. (USA), no.3818, 1 pp. (1 June 1983).

Presents total visual magnitude estimates for the period 1983 May 5-17.

78876 Comet Sugano-Saigusa-Fujikawa (1983e). J.D.Shanklin, J.E.Bortle, C.S.Morris, J.-C.Merlin, Y.Sheffer, N.Ishiyama, E.Everhart, R.E.McCrosky, C.-Y.Shao, B.G.Marsden.

I.A.U. Circ. (USA), no.3819, 1 pp. (1 June 1983).

Reports total visual magnitude estimates for 1983 May 12-24, precise positions for May 9-29, improved parabolic orbital elements based on 27 observations (May 9-29), and an ephemeris for the period 1983 June 3-8 at daily intervals.

78877 Comet Sugano-Saigusa-Fujikawa (1983e). B.G.Marsden.

I.A.U. Circ. (USA), no.3820, 1 pp. (1 June 1983).

Continues the ephemeris given on IAU Circ no.3819 for the period 1983 June 8-17 at 6-hourly intervals. (1 ref.)

96.50K Meteors, showers and meteoroids

78878 Fireball of 1981 May 25. H.Miles (Dept. of Math., Coventry Polytech., Coventry, England).

J. Br. Astron. Assoc. (GB), vol.93, no.3, p.111-13 (April 1983).

On 1981 May 25, at 2217 UT, a brilliant fireball was observed to cross southern England and South Wales. Observations were received from an area covering the whole of southern England, the Midlands and as far north as Lancashire and Yorkshire, together with a large number from South Wales. The fireball travelled on a heading of 311° passing directly over Christchurch (Hants) and Cardiff. It descended at an angle of 15° . When first observed it was at a height of about 100 km and extinction took place just west of Llandeilo (Dyfed) at a height of 12 km. (no refs.)

Comet IRAS-Araki-Alcock (1983d) See Entry 78872

96.50M Meteorites, micrometeorites

78879 U-Th-Pb in chondrites—evidence of elemental mobilities and the singularity of primordial Pb. F.Tera (Dept. of Terrestrial Magnetism, Carnegie Instn. of Washington, Washington, DC, USA).

Earth & Planet. Sci. Lett. (Netherlands), vol.63, no.2, p.147-66 (May 1983).

A unified graphical approach that emphasizes the strict corollarity in the U-Th-Pb systematics and projects subtle diagnostic deviations from it has been adopted for the evaluation of the existing data base. It has been revealed that: (1) Excess radiogenic Pb in chondrites is largely an artifact stemming from Pb contamination of some samples and apparent recent U loss from other samples. (2) Taken at face value, the data indicate that recent U-Th mobility on the chondrule-scale is pervasive in Allende. (3) Allende carries the isotopic imprints of recent multiple disturbances in which elemental mobilities were effected but not isotopic homogenization of Pb. (4) For Allende, the Pb isotope pattern of the matrix samples suggests terrestrial contamination. If this is the case, the systematics indicates for the matrix recent U gain as well. The U-rich chondrules and inclusions, whose discordance is often consistent with U loss, are the probable source. (5) Canyon Diablo primitive Pb appears to represent the primordial composition from which chondritic Pb evolved. (35 refs.)

78880 Nickel isotopic studies in meteorites. P.Morand, C.J.Allegre (Dept. des Sci. de la Terre, Univ. de Paris VI et VII, Paris, France).

Earth & Planet. Sci. Lett. (Netherlands), vol.63, no.2, p.167-76 (May 1983).

The nickel isotopic composition of meteoritic materials were analysed by high-precision mass spectrometry. The samples analyzed include almost all meteorite types for which large isotopic anomalies have been reported for oxygen, silver, magnesium and titanium. These samples are C_1 , C_3 , L, LL, H and E chondrites, IVB irons, Eagle Station pallasite and inclusion, matrix and 'whole rock' samples of the Allende meteorite. The result is that isotope anomalies were not found for nickel within the experimental accuracy. (43 refs.)

78881 Ni isotopic compositions in Allende and other meteorites. T.Shimamura, G.W.Lugmair (Dept. of Chem., Univ. of California, San Diego, La Jolla, CA, USA).

Earth & Planet. Sci. Lett. (Netherlands), vol.63, no.2, p.177-88 (May 1983). A new technique for high-precision isotopic analyses of Ni was developed and applied to terrestrial samples, Allende inclusions and materials from other meteorites. The Ni isotopic abundances are indistinguishable from normal within presently obtainable precision with only one possible exception. The latter inclusion has to contain a significantly fractionated magnesium isotopic pattern of 9 per mille/amu. A normal Ni isotopic pattern has also been observed for the chromite/carbon fraction of an Allende acid residue. All other meteoritic samples analysed (Kohar matrix and chondrules, Murray matrix, a Tieschitz chondrule and an Orgueil magnetic fraction) all show normal isotopic compositions of Ni; no evidence for effects from now extinct ^{60}Fe could be detected. (40 refs.)

78882 Cooling history of pyroxene chondrules in the Yamato-74191 chondrite (L3)—an electron microscopic study. M.Kitamura, M.Yasuda, S.Watanabe, N.Morimoto (Dept. of Geology & Mineralogy, Kyoto Univ., Sakyo, Japan).

Earth & Planet. Sci. Lett. (Netherlands), vol.63, no.2, p.189-201 (May 1983). Fine textures of clinopyroxene in an extroradial pyroxene chondrule (EPC) and a comb-like pyroxene chondrule (CPC) in the Yamato-74191 chondrite (L3) have been studied by analytical electron microscopy. Both pyroxenes consist of three regions different in composition and texture; core, mantle and marginal regions, though the pyroxenes of the CPC are more Fe-rich than those of the EPC. The core region is the most Mg-rich with no Ca component and commonly shows polysynthetic (100) twins. The polysynthetic twins, cracks and subgrain boundaries in the core in the EPC and CPC must have formed during the transition from proto-type to clino-type pyroxenes. The exsolution textures in the mantle and marginal regions indicate initial crystallization of pigeonite-C followed by decomposition into pigeonite-P and augite. The periodicity of 15-20 nm in the spinodal decomposition textures indicates that the cooling rate of the pyroxenes, when passing through about 1000°C, was of the order of a few tens to several degrees centigrade per hour. The cooling history of the chondrules has been explained by a monotonous cooling controlled by the cooling rate of the surrounding medium. (29 refs.)

78883 Measurement of ^{53}Mn in deep-sea iron and stony spherules. K.Nishizumi (Dept. of Chem., Univ. of California, San Diego, CA, USA). *Earth & Planet. Sci. Lett. (Netherlands)*, vol.63, no.2, p.223-8 (May 1983). Cosmic-ray-produced ^{53}Mn ($t_{1/2}=3.7 \times 10^6$ years) was measured in individual and groups of deep-sea iron and stony spherules by highly sensitive neutron activation analysis. The activities found were less than 20 dpm $^{53}\text{Mn}/\text{kg Fe}$ (10^{-5} – 10^{-6} dpm $^{53}\text{Mn}/\text{sample}$) in iron spherules except one iron spherule whose activity was 241 ± 73 dpm $^{53}\text{Mn}/\text{kg Fe}$. These low activities may indicate evaporative loss of ^{53}Mn due to heating in the Earth's atmosphere. On the other hand, all stony spherules contained 200-260 dpm $^{53}\text{Mn}/\text{kg Fe}$ which is similar to chondritic values. These spherules may be ablation debris from large objects. (22 refs.)

78884 On the fine structure of meteoritic taenite/tetrataenite and its interpretation. J.F.Albertsen (Phys. Lab. I, H.C. Orsted Institute, Copenhagen, Denmark), H.P.Nielsen, V.F.Buchwald.

Phys. Scr. (Sweden), vol.27, no.4, p.314-20 (April 1983). Taenite fields from several meteorites have been investigated by TEM, electron microprobe and Mossbauer spectroscopy. The investigations have disclosed a delicate pattern of antiphase domains in the tetrataenite and the presence of low-Ni taenite at the antiphase boundaries, in what was hitherto believed to be pure tetrataenite. The observations indicate that the 'cloudy taenite' (cloudy zone II) was formed by a magnetically induced spinodal decomposition of the metastable taenite during slow cooling below 400°C. As recently demonstrated such a decomposition is likely to occur when the Curie-temperature of the alloy changes rapidly with composition, as it does in f.c.c. iron-nickel alloys containing approximately 28-43% Ni. (All compositions in weight %). The large contribution to Gibbs free energy from magnetic ordering gives rise to inflections in the Gibbs free energy curve, making the alloy unstable towards decomposition, here into a magnetically and atomically ordered Ni-rich alloy plus a magnetically and atomically disordered Ni-poor alloy. The model accounts apparently well for the structure and composition of the two phases in the cloudy taenite, and also for the peculiar response of f.c.c. iron-nickel alloys to irradiation with energetic neutrons or electrons at temperatures below 400°C. (23 refs.)

The dissipation of a sodium cloud See Entry 78727

96.60 SOLAR PHYSICS

78885 Structure and spectrum of quiescent prominences IV. The ultraviolet ionization continua of hydrogen and helium. J.N.Heasley, R.W.Milkey (Inst. for Astron., Univ. of Hawaii, Honolulu, HI, USA).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.398-402 (1 May 1983). For pt.III see *ibid.*, vol.221, no.2, pt.1, p.677-88 (1978). Examines the formation of the ground-state ionization continua of hydrogen (A912) and helium (A504) and the information about the physical state of the prominence which can be obtained from observation of these features. (10 refs.)

78886 A coronal transient associated with a high-speed type II burst. T.E.Gergely, M.R.Kundu (Clark Lake Radio Obs., Univ. of Maryland, College Park, MD, USA), E.Hildner.

Astrophys. J. (USA), vol.268, no.1, pt.1, p.403-11 (1 May 1983). Discusses several characteristics of a white light transient observed by the ATM Coronagraph experiment aboard Skylab. The transient was associated with a very high speed type II radio burst. Based on the relative speeds of the transient and the radio burst, the type II disturbance must have propagated in a still undisturbed corona, at an $\sim 35^\circ$ angle to the preexisting streamer and along an essentially open field configuration. The electron density gradients derived from the radio and the white light observations are compared. The assumption that the type II was a weak MHD shock leads to large values for the coronal magnetic field. The type II radiation may have originated in a strong shock, of magnetic Mach number $M > 2$. (24 refs.)

78887 Magnetohydrostatic model of solar faculae. V.A.Osherovich (Environmental Res. Lab., NOAA, Boulder, CO, USA), T.Fla, G.A.Chapman.

Astrophys. J. (USA), vol.268, no.1, pt.1, p.412-19 (1 May 1983). A self-similar magnetohydrostatic model of solar faculae is presented. The model is based on the Schluter-Temesvary equation, originally derived for sunspots. Magnetic tension and twisted magnetic field are taken into account. The exact magnetohydrostatic solution obtained from an observability derived pressure deficit basically Chapman's semiempirical facular model without tension. The difference between a facula and a sunspot and the thermodynamic consequences of a twisted magnetic field are discussed. Pressure and temperature profiles at different heights are presented. (15 refs.)

78888 Underground science at Homestake [solar neutrino experiment]. R.Davis, Jr., B.T.Cleveland, J.K.Rowley (Brookhaven Nat. Lab., Upton, NY, USA).

AIP Conf. Proc. (USA), no.96, p.2-15 (1982). [received: May 1983] (Workshop on Science Underground, Los Alamos, CA, USA, 1982).

A brief overview is given of some of the scientific work that has been done in the Homestake mine. The problems and advantages of working in active mines are discussed. Some details on the construction of the chlorine solar neutrino experiment are presented and the current results of this experiment are given. The report concludes with a discussion of the importance and feasibility of a much larger chlorine experiment. (15 refs.)

78889 The analysis of solar models—neutrinos and oscillations. R.K.Ulrich (Univ. of California, Los Angeles, CA, USA), E.J.Rhodes, Jr., S.Tomeczek, P.J.Dumont, W.M.Brunish.

AIP Conf. Proc. (USA), no.96, p.66-79 (1982). [received: May 1983] (Workshop on Science Underground, Los Alamos, CA, USA, 1982).

The theory of stellar structure and evolution is used to calculate the properties of a variety of objects from red giants and supernova precursors to white dwarfs and neutron stars. Accurate tests of the theory in the context of these applications are generally not available. The Sun as the nearest star provides a unique example of a star which can be subjected to a variety of precise tests not possible with remote stars. The authors concentrate on two of these tests, solar neutrinos and solar oscillations, which currently indicate that there is something seriously wrong with our standard solar model. (20 refs.)

78890 The case of the missing solar neutrinos. W.A.Fowler (Will Keith Kellogg Radiation Lab., California Inst. of Technol., Pasadena, CA, USA).

AIP Conf. Proc. (USA), no.96, p.80-7 (1982). [received: May 1983] (Workshop on Science Underground, Los Alamos, CA, USA, 1982).

Observations employing the Cl-Ar technique find only one-fourth the neutrino flux from the Sun at the Earth expected on the basis of standard solar models and the rates of the nuclear reactions which fuse hydrogen into helium as measured in terrestrial laboratories. The current situation concerning nuclear reaction rates is discussed. It is concluded that the Ga-Ge technique which will detect the model and reaction rate independent flux of pp-neutrinos from the Sun should be put into full-scale operation as soon as possible. Other techniques which will probably require a National Underground Science Facility are discussed briefly. (15 refs.)

78891 A radiochemical solar neutrino experiment using $^{81}\text{Br}(\nu_e)^{81}\text{Kr}$. G.S.Hurst, C.H.Chen, S.D.Kramer, M.G.Payne (Health & Safety Res. Div., Oak Ridge Nat. Lab., Oak Ridge, TN, USA), R.D.Willis.

AIP Conf. Proc. (USA), no.96, p.96-104 (1982). [received: May 1983] (Workshop on Science Underground, Los Alamos, CA, USA, 1982).

Both geochemical and radiochemical experiments based on the interaction $^{81}\text{Br}(\nu_e)^{81}\text{Kr}$ to detect ^8Be solar neutrinos have been suggested as a logical extension of the ^{37}Cl experiment of Davis et al. The ^{81}Br experiment, however, requires the development of a direct counter for the slowly decaying ^{81}Kr . Progress toward such a detector based on resonance ionization spectroscopy (RIS) is discussed. (24 refs.)

78892 A proposed geological solar neutrino measurement. G.A.Cowan, W.C.Haxton (Los Alamos Nat. Lab., Los Alamos, NM, USA).

AIP Conf. Proc. (USA), no.96, p.105-8 (1982). [received: May 1983] (Workshop on Science Underground, Los Alamos, CA, USA, 1982).

It may be possible to measure the boron-8 solar neutrino flux, averaged over the past several million years, from the concentration of technetium-98 in molybdenum-rich ore. This geochemical experiment could provide the first test of nonstandard solar models that suggest a relation between the chlorine-37 solar neutrino puzzle and the most recent glacial epoch. The necessary conditions for achieving a meaningful measurement are identified and discussed. (7 refs.)

78893 Solar emission lines near 12 microns. J.Brault (Kitt Peak Nat. Obs., Tucson, AZ, USA), R.Noyes.

Astrophys. J. Lett. Ed. (USA), vol.269, no.2, pt.2, p.L61-6 (15 June 1983).

The newly discovered 12 μm emission lines in the solar spectrum are found to vary strongly with position on the solar disk. The two strongest lines strengthen greatly toward the limb and disappear in spot umbrae. They show pronounced splitting in spot penumbrae and plages, characteristic of simple Zeeman triplets with $g \sim 1$. Their narrow line profiles suggest a chromospheric rather than coronal origin, but the lines remain unidentified. Forty-one additional unidentified far-infrared solar emission lines are reported. Potential uses of the lines for astrophysical investigations are noted. (5 refs.)

78894 Direct evidence of type III electron streams propagating in coronal streamers. M.R.Kundu, T.E.Gergely, P.J.Turner (Astron. Program, Clark Lane Radio Obs., Univ. of Maryland, College Park, MD, USA), R.A.Howard.

Astrophys. J. Lett. Ed. (USA), vol.269, no.2, pt.2, p.L67-71 (15 June 1983).

Using two-dimensional solar images at 73.8 MHz, obtained with the Clark Lake Multifrequency Radioheliograph. The authors present direct evidence that type III electron streams propagate in dense coronal streamers. This evidence is substantiated by the excellent coincidence that the authors find in position angle between the densest parts of streamers observed with the Solwind coronagraph on the P78-1 satellite and the maximum brightness of type III burst sources. (15 refs.)

78895 Observations of the Sun with the CERGA astrolabe in 1981. F.Laclare, M.Glentzlin (Centre d'Etudes et de Recherches Géodynamiques et Astron., Grasse, France).

Astron. & Astrophys. Suppl. Ser. (France), vol.52, no.2, p.265-7 (May 1983). In French.

The results of a new campaign of solar position observations are reported. For computation procedures the authors use latitudes and times published by the B.I.H. The accuracy obtained for one measurement is $0.020''$ for $\Delta\alpha$ and $0.18''$ for $\Delta\delta$. (4 refs.)

78896 Time structure of solar decametric type III radio bursts. G.Thejappa, C.V.Sastry (Indian Inst. of Astrophys., Bangalore, India).

J. Astrophys. & Astron. (India), vol.3, no.2, p.151-9 (June 1982). [received: June 1983]

The time structure of solar radio decametric type III bursts occurring during the periods of enhanced emission is investigated. It is found that the time profiles can take a variety of forms of which three distinct types are the following: (1) profiles where the intensity rises to a small but steady value before the onset of the main burst, (2) the intensity of the main burst reduces to a finite level and remains steady before it decays to the base level, (3) the steady state is present during the rise as well as the decay phase of the main burst. It is shown that these profiles are not due to random superposition of bursts with varying amplitudes. They are also probably not manifestations of fundamental-harmonic pairs. (15 refs.)

78897 Could ${}^7\text{Be}$ be destroyed by neutron absorption in the Sun? A note on the solar neutrino puzzle. Huang Zu-qia (Low Energy Nuclear Phys. Inst., Beijing Normal Univ., Beijing, China).

Commun. Theor. Phys. (China), vol.1, no.4, p.527-30 (1982).

A comparison is made between the rate of the ${}^7\text{Be}(\text{p},\gamma){}^8\text{B}$ reaction and the rate of the neutron absorption reaction ${}^7\text{Be}(\text{n,p}){}^7\text{Li}$ which might have been important in destroying ${}^7\text{Be}$ in the solar interior. (5 refs.)

78898 Computer reduction of solar whole disk drawings. L.M.Dougherty, F.Dyson, M.D.Fickling (Ravenstone Obs., Percival Whitley Coll., Halifax, England).

J. Br. Astron. Assoc. (GB), vol.93, no.3, p.117-19 (April 1983).

The work-load and the boredom of reducing the large number of solar whole disk drawings within the Solar Section are outlined. The authors report the earlier practice and draw attention to its shortcomings. After reporting the investigation to seek alternative techniques the authors present the current computer reduction program as suitable for use by individual observers with stand-alone microcomputers such as those commonly available in the high street shops. (17 refs.)

78899 Evidence for a distorted solar core rotating with a 12.4-day period.

R.H.Dicke (Phys. Dept., Princeton Univ., Princeton, NJ, USA).

Nature (GB), vol.303, no.5915, p.292-5 (26 May 1983).

The periodicity discovered in the solar Doppler velocity may be due to an Eddington-Sweet current driven in the photosphere by a distorted gravitational potential rotating rigidly with a synodic period of 12.81 ± 0.10 days (12.4 days sidereal). (14 refs.)

97.00 STARS

97.10 STELLAR CHARACTERISTICS

78900 Infall and outflow of S^{+3} ions in 15 Monocerotis, tau Canis Majoris, and iota Orionis. D.C.Morton (Anglo-Australian Obs., Epping, NSW, Australia).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.217-24 (1 May 1983).

High-resolution Copernicus scans (0.051 Å FWHM) in 1980 from 1061.8 to 1064.6 Å and 1072.1 to 1074.9 Å along with short scans in 1972 or 1973 from 1062.4 to 1063.0 Å are used to check the report by Snow and Morton (1976) of infalling S IV ions in 15 Mon (O7 V), τ CMa (O9 II), and ι Ori (O9 III). The original lower resolution data are found to be misleading. Nevertheless, a shift of about $+50 \text{ km s}^{-1}$ in 1972 is confirmed in ι Ori, and a possible shift of about $+15 \text{ km s}^{-1}$ in 1973 is suspected in τ CMa. However, by 1980 the S IV in both stars had changed to outflow velocities somewhere between -30 and -140 km s^{-1} . On both occasions, 15 Mon showed no evidence of shifts. New data also have been obtained on the interstellar absorption of S IV, C II, and Fe II toward these stars. (28 refs.)

78901 Differential rotation in F stars: a comparison between theory and observation. G.Belvedere (Istituto di Astron., Univ. di Catania, Catania, Italy), L.Paterno.

Astrophys. J. (USA), vol.268, no.1, pt.1, p.246-9 (1 May 1983).

Gray (1982) recently observed seven stars on or slightly above the main sequence in the spectral region between F2 and F8, looking at the Fourier transforms of their line profiles. His observations show no or very small differential rotation in the examined stars, contradicting the theoretical predictions of Belvedere et al. (1980). However, in the spectral range examined by Gray, only an F5 V model was computed, adopting for it the standard equatorial velocity of 30 km s^{-1} , thus guessing the differential rotation behavior of main-sequence stars between F5 and G2 (Sun) by simply connecting these two models with a convenient curve. The authors compute models for each star Gray observed, using the same differential rotation computer code as in Belvedere et al. and the observed rotational velocities given by Gray. The results are explained and discussed on the basis of interaction of rotation with convection and also in the framework of the very recent observations by Wohl (1983). (5 refs.)

78902 The luminosity-core mass relation: why and how. Tuchman Y., A.Glasner, Z.Barkat (Racah Inst. of Phys., Hebrew Univ. of Jerusalem, Jerusalem, Israel).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.356-60 (1 May 1983).

Shows how relevant stellar structure parameters establish the luminosity-core mass relation. (15 refs.)

78903 Enhancement of thermonuclear reaction rate due to screening by relativistic degenerate electrons. S.Ichmaru, K.Utsumi (Dept. of Phys., Univ. of Tokyo, Tokyo, Japan).

Astrophys. J. Lett. Ed. (USA), vol.269, no.2, pt.2, p.L51-5 (15 June 1983).

Contrary to the prevailing view based on a qualitative argument, it is shown through quantitative analyses that the screening effect of the relativistic degenerate electrons does produce a significantly large contribution to the enhancement factor of the thermonuclear reaction rate in the dense stellar matter. Physically, this feature stems from the fact that the relativistic effect acts to enhance the screening by 'softening' the electrons against compression. The computed results for the enhancement factor are parameterized in a form of analytic formulae to facilitate practical uses in the calculations of stellar evolution. (13 refs.)

78904 Physical processes determining stellar chromospheres structure. II. Z.Musielak (Inst. Fizyki Teoretycznej i Astrofizyki Uniwersytetu Gdanskiego, Gdansk, Poland).

Postępy Astron. (Poland), vol.30, no.3-4, p.269-92 (July-Dec. 1982). In Polish. [received: April 1983]

Observational data and some correlations between chromospheric and other atmospheric parameters are discussed. The construction of models of solar and stellar chromospheres is described. These theoretical models are based on the energy balance between radiative losses and the amount of dissipated mechanical energy. Some problems of inhomogeneity of the theoretical models as well as evolutionary effects are discussed. (47 refs.)

78905 Thirteen-color photometry of O stars. W.J.Schuster (Inst. de Astron., Univ. Nacional Autónoma de Mexico, Mexico City, Mexico).

Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.3, p.137-48 (July 1982). [received: April 1983]

Thirteen-color photometry for O stars (spectral types B2 and earlier) are presented. Partial data (8C or 6RC) for 27 stars and complete 13-C data for 33 stars are included. (16 refs.)

78906 On the intensity and shape of radio recombination lines from ionized stellar winds. L.F.Rodriguez (Inst. de Astron., Univ. Nacional Autónoma de Mexico, Mexico City, Mexico).

Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.3, p.179-82 (July 1982). [received: April 1983]

The ionized wind of early-type stars emit continuum (free-free) radiation that has been detected in the radio frequencies for an appreciable number of stars. The measurement of this continuum emission allows a reliable determination of the ratio of mass-loss rate to wind terminal velocity: \dot{M}/V_∞ . These winds should also emit very weak and wide radio recombination lines. The detection of these lines would allow a determination of V_∞ and \dot{M} separately. The author calculates the expected intensity and shape of these lines. For typical winds the lines are too weak and wide to be detected with presently available instruments. However, stellar winds with peculiarly low terminal velocities may have detectable radio recombination line emission. In particular, lines have been detected recently in MWC 349. The author discusses the line characteristics of this source. (11 refs.)

97.20 NORMAL STARS (BY CLASS): GENERAL OR INDIVIDUAL

- 78907 Survey of H α emission in globular cluster red giants. C.Cacciari (Astron. Div., ESTEC, Villafranca, Spain), K.C.Freeman. *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.185-94 (1 May 1983). From a spectroscopic survey (resolution 0.67 Å) of 143 red giants of 12 globular clusters and three open clusters, direct evidence of H α emission was found for about one-third of the stars brighter than log (L/L_{\odot})=2.9. There is no clear dependence of H α emission (or mass loss rate) on metallicity. A few stars were observed many times over an interval of about 1 year, and there is clear evidence that the H α emission is variable. From the distribution of stars in the log H α - M_{bol} plane (H_0 is the corrected FWHM for the apparent H α absorption feature), the authors suggest that weak H α emission (i.e. a lower rate of mass loss) may be present in most globular cluster giants with log (L/L_{\odot}) between 2.9 and 2.3 and perhaps even fainter. The authors argue that this H α emission is associated with the main part of the pre-horizontal-branch mass loss. (65 refs.)
- 78908 Simultaneous X-ray and ultraviolet observations of ϵ Orionis and κ Orionis. J.P.Cassinelli (Washburn Obs., Univ. of Wisconsin, Madison, WI, USA), L.Hartmann, W.T.Sanders, A.K.Dupree, R.V.Myers. *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.205-16 (1 May 1983). Simultaneous observations were made with the Einstein Observatory, the International Ultraviolet Explorer, and the Copernicus satellite of the supergiant stars ϵ Ori (B0 Ia) and κ Ori (B0.5 Ia). No variations were detected in the X-ray flux or spectrum or in the ultraviolet line profiles of Auger enhanced ionization states. For ϵ Ori, the X-ray count rate was the same as it was during an observation 11 months earlier, while for κ Ori, the X-ray count rate was 46% larger than it was 11 months earlier. This change could be explained by an increase in the source temperature from 10^6 K to $10^{6.4}$ K, or by an increase in the source emission measure of 46%, or by a decrease in the column density of the intervening matter of several times 10^{20} cm⁻². The ultraviolet line profiles are found to be insensitive to changes of X-ray flux which are less than 50%. Various constraints imposed on current models for the X-ray production in early-type stars are discussed. (43 refs.)
- 78909 On the nature of upsilon Sagittarii. D.Schonberger, I.S.Drilling (Louisiana State Univ. Obs., Baton Rouge, LA, USA). *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.225-7 (1 May 1983). Presents a new explanation for the nature and evolution of the extremely hydrogen-deficient binary ν Sgr which is consistent with all observational and theoretical facts. First, the system goes through a case B mass exchange in which most of the hydrogen-rich envelope of a massive primary (5-14 M_{\odot}) is lost. The remaining envelope still contains ~50% hydrogen (by number), but is now of negligible mass, so that the star will evolve like a pure helium star. If its mass is between 1 and 2 M_{\odot} , the star will reach low surface temperatures and become a supergiant before the onset of carbon burning. This star (the original primary) will then fill its Roche lobe a second time, spilling its now helium-rich envelope over onto the secondary (case BB mass exchange). The authors argue that ν Sgr is in this state at the present time, and that the visible star is an evolved helium star of ~1 M_{\odot} with a degenerate carbon-oxygen core and a helium-burning shell which provides the high luminosity. (24 refs.)
- 78910 Observations of ultraviolet carbon lines in the spectra of three DC white dwarfs. G.Wegner (Dept. of Astron., Pennsylvania State Univ., University Park, PA, USA). *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.282-90 (1 May 1983). Ultraviolet spectra of three DC white dwarfs have been obtained using the International Ultraviolet Explorer satellite (IUE). These objects are LDS 275A (=EG 66=0935-37), G187-15 (=LTT 16151=EG 262=2059+31), and L 791-40 (=LTT 9491=EG 264=2317-17). All three show the strong ultraviolet lines of neutral carbon recently found in the spectra of a number of other DC stars. Published observations of LDS 275B and G187-15 establish that they have continuous visual spectra, while recent scans of L791-40 and G187-15 show weak $\lambda\lambda 4472$ and 5876 lines of neutral helium and possibly the (0, 0) Swan band of C₂, respectively. These new objects enlarge the sample of degenerates already known to have atmospheres containing carbon, either from visual or ultraviolet observations. When this type of white dwarf is plotted along with the other spectral classes in the Stromgren two-color diagram, it appears that white dwarfs observed having

carbon occupy a restricted region, and no C₂ white dwarfs occur that are cooler than $T_{\text{eff}} \approx 6800$ K. (37 refs.)

- 78911 Stellar diameter measurements by two-aperture interferometry in the infrared. G.P.di Benedetto, G.Conti (Istituto di Fisica Cosmica, CNR, Milano, Italy). *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.309-18 (1 May 1983). Angular diameters of the giant stars α Boo, α Tau, γ Dra, β And, and μ Gem are measured at 2.2 μ m wavelength by the Michelson method. Near the first null, the percentage of visibility is determined to within an accuracy of a few hundredths. It follows that angular dimensions can be derived with a relative error of few percent, even with a poor point source calibration. For the bright α Tau a clear secondary maximum is also found in the visibility function. Effective temperatures are also derived for the observed stars. A new temperature of $T_{\text{eff}} = 4240 \pm 118$ K is determined for the important star α Boo, and implications on the existing models are then discussed. (47 refs.)
- 78912 The pulsation properties of DB white dwarfs: a preliminary analysis. D.E.Winget (McDonald Obs. & Dept. of Astron., Univ. of Texas, Austin, TX, USA), H.M.Van Horn, M.Tassoul, C.J.Hansen, G.Fontaine. *Astrophys. J. Lett. Ed. (USA)*, vol.268, no.1, pt.2, p.L33-6 (1 May 1983). Reports preliminary results of a numerical investigation of the nonradial g-mode pulsation properties of evolutionary DB white dwarf models. The authors solve the fully nonadiabatic equations for modes corresponding to spherical harmonic index $l=1$ through 3. For each of the sequences of models examined ($M_{\text{He}} = 0.6 M_{\odot}$; and helium layer masses of $10^{-6} M_{\text{He}}$ and $10^{-4} M_{\text{He}}$), the authors find a nonradial g-mode instability strip about 3000K wide. For models with standard ML1 convection, this strip lies in the effective temperature range 19000 K $\geq T_{\text{eff}} \geq 16000$ K. The boundaries of the instability strip are extremely sensitive to the assumed efficiency of convection, however, and for sequences with more efficient (ML3) convection, the authors find the instability strip to be in the range 29000K $\geq T_{\text{eff}} \geq 26000$ K. Extrapolation of the calculations to 0.4 M_{\odot} and 0.9 M_{\odot} indicates that the instability strip boundaries are insensitive to uncertainties in the total stellar mass. The most unstable modes have e-folding times of the order of days. (15 refs.)
- 78913 A photometric atlas of the spectrum of γ Tauri $\lambda\lambda$ 5186-8700 Å. L.Appelquist (Copenhagen Univ. Obs., Copenhagen, Denmark), J.Andersen, W.A.Fisher, J.M.Fletcher, P.Kjaergaard. *Astron. & Astrophys. Suppl. Ser. (France)*, vol.52, no.2, p.237-63 (May 1983). A photometric atlas has been prepared of the spectrum of the K giant γ Tau, covering the wavelength range 5186-8700 Å and thus supplementing that for the blue-green region by Gratton et al. (1975). Based on spectrograms of dispersion 4.9 Å/mm obtained with the 1.2 m telescope and coude spectrograph of the Dominion Astrophysical Observatory, the atlas is the first in a set of four comprising also α Boo, ρ Boo, and δ Boo A, that will illustrate separately the effects upon the spectrum of variations in temperature and metal abundance. The region 7000-8685 Å is shown in extenso. The full atlas is available on magnetic tape from the Stellar Data Center at Strasbourg. (19 refs.)

97.30 VARIABLE AND PECULIAR STARS (inc. novae)

- 78914 A survey of spectral morphology and rotational velocities among the helium-rich stars. N.R.Walborn (Lab. for Astron. & Solar Phys., Goddard Space Flight Center, Greenbelt, MD, USA). *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.195-204 (1 May 1983). A morphologically homogeneous list of the helium-rich B stars is given: according to the present criteria, 20 members of this category brighter than 10th magnitude are known, all but one of which have been newly observed. Three 11th magnitude helium-rich stars are also noted; other objects previously associated with the helium-rich category which do not meet the present criteria are listed separately. Equivalent widths of hydrogen, helium, and metal lines in the spectra of the helium-rich and comparison stars are given. Uniform determinations of the projected rotational velocities are also made for the helium-rich stars. The distribution of their rotational velocities, and in particular the often noted 'predominance' of slow rotators, is found to be indistinguishable from that of normal early B dwarfs, except for a possible excess of rapid ($v \sin i \sim 160$ km s⁻¹) rotators which, however, depends upon only two or three stars. Two questions are critically discussed. (1) Are there any metal abundance anomalies in the helium-rich spectra or not? (2) Are the helium-rich stars massive ($\sim 10 M_{\odot}$) Population I objects with normal main-sequence cores and surface helium enhancements, or are they low-mass ($1-4 M_{\odot}$), highly evolved objects with processed cores? (44 refs.)

- 78915 The spectra of Wolf-Rayet stars. I. Optical line strengths and the hydrogen-to-helium ratios in WN type stars.** P.S.Conti, E.M.Eeep, D.N.Perry (Joint Inst. for Lab. Astrophys., Univ. of Colorado, Boulder, CO, USA). *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.228-45 (1 May 1983). Studies spectra of Wolf-Rayet stars by examining the optical line strengths of WN stars in the Galaxy and the Large Magellanic Cloud to see what similarities and differences exist among them. Tables of equivalent widths extracted from spectra are presented and some conclusions are drawn. There is a wide dispersion in line strengths for all ions even among stars of the same subtype, with WN 7 stars weaker overall than surrounding types. Nitrogen line ratios indicate that the WN subtypes represent an ionization sequence, but one with considerable overlap: the classification scheme is not single valued; other physical parameters must play a role. The Balmer-Pickering decrement is used to estimate the H/He ratio for most of the WN stars with available spectra. The abundance of H probably relates to structural differences in the winds that, in part, give rise to a dispersion in observed line strengths. The authors estimate the C/N ratio. In most cases the observations suggest that the C/N ratio is consistent with 'evolved' models for WN stars. (42 refs.)
- 78916 Observational studies of the symbiotic stars. II. Emission-line relative intensity variations in CI Cygni, BF Cygni, AX Persei, and V1016 Cygni.** N.A.Oliver, C.M.Anderson (Washburn Obs., Univ. of Wisconsin, Madison, WI, USA). *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.250-63 (1 May 1983). For pt.1 see ibid. vol.242, no.1, p.188-94 (1980). Low-resolution spectra ($\lambda\lambda 3800-5900$) are presented of the symbiotic stars CI Cygni, BF Cygni, AX Persei, and V1016 Cygni, which were obtained with the Washburn Observatory Boller and Chivens Cassegrain spectrograph and intensified Reticon. The nebular electron temperature and density are derived from the [O III] $\lambda 5007$ and $\lambda 4363$ emission lines and the UV intercombination lines of $\lambda 1661$ and $\lambda 1667$. Relative emission-line intensity variations were observed in all four stars. The relative emission line changes correlated with photometric minima for CI Cyg, AX Per, and possibly BF Cyg. These changes are interpreted as due to a red giant eclipsing a nebula surrounding the exciting source. A decline in the intensity ratios of [Ne III] $\lambda 3869$ to [O III] and He I $\lambda 5876$ to [O III] $\lambda 5007$ were also observed during the 1980 minimum of CI Cyg. (37 refs.)
- 78917 The binary nature of the barium stars. II. Velocities, binary frequency, and preliminary orbits.** R.D.McClure (Dominion Astrophys. Obs., Herzberg Inst. of Astrophys., Victoria, BC, Canada). *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.264-73 (1 May 1983). For pt.1 see *Astrophys. J. Lett. Ed. (USA)*, vol.238, no.1, p.L35-8 (1980). A series of radial velocity observations has been obtained over the last 3 years of a sample of 20 Ba II stars. Seventeen of these (85%) are found to show long-term velocity variations ranging in amplitude from a few to tens of km s⁻¹. Thus it seems likely that all Ba II stars are binary systems. An additional Ba II star in the open cluster NGC 2420 is also found to have a variable velocity. Orbits for seven Ba II stars indicate low-mass companions, compatible with their being white dwarfs. Separations are large, about 2 AU on average. The peculiar abundances are not explained, but the fact remains that multiplicity must bear a causal relationship to these peculiarities. (36 refs.)
- 78918 Angular momentum loss and the evolution of cataclysmic binaries.** R.E.Taam (Dept. of Phys. & Astron., Northwestern Univ., Evanston, IL, USA). *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.361-7 (1 May 1983). Considers the influence of angular momentum losses on the evolution of low-mass binary systems with collapsed companions; specifically losses due to magnetically coupled stellar winds, to mass ejection associated with nova explosions, and to gravitational radiation. All evolutionary sequences are found to evolve ultimately to shorter orbital periods since angular momentum losses are effective in outweighing the effects of mass transfer from the less massive to the more massive component. Typical mass transfer rates, induced by the loss of angular momentum associated with magnetically coupled winds, are $\geq 10^{-5} M_{\odot} \text{ yr}^{-1}$. If the empirical braking law for cool main-sequence stars can be applied to the entire lower main sequence, it is found that angular momentum loss via winds dominates gravitational radiation losses in promoting mass transfer in a binary for secondaries $\geq 0.1 M_{\odot}$. (27 refs.)
- 78919 A spectroscopic study of four late-type galactic WN stars: the question of duplicity.** R.L.Lamontagne, A.F.J.Moffat (Dept. de Phys., Univ. de Montreal, Montreal, Quebec, Canada), W.Seggewiss. *Astrophys. J. (USA)*, vol.269, no.2, pt.1, p.596-604 (15 June 1983). Spectroscopic observations of four late-type galactic WN stars (WNL) indicate that MR 122, MR 119, and HDE 313846 are probably single stars and that HD 177230 may be a binary system with a low-mass, probably compact companion. The study adds strong support to the hypothesis that, at least among the WNL stars, the duplicity rate of Wolf-Rayet stars is like that of normal stars. Stellar wind is therefore probably the main mechanism that removes the outer layers of an O star as it evolves of a luminous WN star. (26 refs.)
- 78920 Narrow-band photometric periods in SS 433.** S.F.Anderson, B.Margon (Astron. Dept., Univ. of Washington, Seattle, WA, USA), S.A.Grandi. *Astrophys. J. (USA)*, vol.269, no.2, pt.1, p.605-12 (15 June 1983). Analyzes the variation of the ratio of the rest-wavelength ('stationary') H α emission-line flux to continuum strength in SS 433 on 200 spectra obtained during a four-year interval from 1978 to 1982. Fourier and least-squares analyses reveal four highly significant periods: at 162 ± 1 , 81 ± 1 , 13.090 ± 0.007 , and 6.545 ± 0.007 days. The authors argue that these observed narrow-band periods are, at least partly, manifestations of broad-band variations reported by other observers; however, several lines of evidence suggest that the line flux also varies periodically. The 13.1 and 6.5 day variations are doubtless eclipse-related analogues of the 13.1 day radial velocity variations which are ascribed to the binary orbital period of the system. The observation of the 162 and 81 day variations are the first highly significant detections of photometric analogues to the large amplitude spectroscopic variations of the relativistic jet in SS 433. The data provide support models where the direction of the ejected jets is directly controlled by the orientation of an accretion disk. Further, the analysis strongly confirms the suggestion of Crampton and Hutchings (1981) that it is the radial velocity curve of the stationary He II $\lambda 4686$ emission (and not that of the stationary Balmer emission) which reflects the true binary orbital motion, and hence that the binary components have rather different masses. The data constrain the mass-loss through the jets. (31 refs.)
- 78921 Infrared photometry and mass loss rates for Of-type stars.** P.Persi, M.Ferrari-Toniolo (Istituto Astrofisica Spaziale, CNR, Frascati, Italy), G.L.Grasdalen. *Astrophys. J. (USA)*, vol.269, no.2, pt.1, p.625-33 (15 June 1983). Using infrared photometry from 2.3 μm up to 10 μm , numerical relations between 10 μm free-free and bound-free emission flux models, and the ratio M/\dot{m}_{∞} developed for different semiempirical wind velocity laws, the authors obtain mass loss rates for 15 Of-type stars, including 10 Of, three O(f) and two O((f)) stars in the spectral type range O4-O8.5. Independent of the spectral type and luminosity, the authors detected a group of stars including HD 108, HD 14947, HD 47129, HD 16691, and Cyg OB2 No.5 with a strong IR excess already present at 2.3 μm . The derived mass loss rates are very similar to the M values obtained for WR stars indicate that radiation pressure alone is sufficient to drive the stellar wind in these Of stars. Three of the most luminous Of stars in the Cyg OB2 association, known to be radio sources, were included in the program stars. (31 refs.)
- 78922 The discovery of nonradial instability strips for hot, evolved stars.** S.G.Starrfield, A.N.Cox (Theoretical Div., Los Alamos Nat. Lab., Los Alamos, NM, USA), S.W.Hodson, W.D.Pennell. *Astrophys. J. Lett. Ed. (USA)*, vol.268, no.1, pt.2, p.L27-32 (1 May 1983). Performs radial and nonradial, linear, nonadiabatic pulsation analyses of model stellar envelopes in the effective temperature range from $8 \times 10^4 \text{ K}$ to $1.5 \times 10^5 \text{ K}$. These models have total masses of $0.6 M_{\odot}$ and radii chosen so that they line up along a pre-white dwarf cooling curve computed by Schonberger (1979). The authors use three different interior compositions: (1) 100% carbon; (2) 50% ^{12}C and 50% ^{16}O (by mass); and (3) 10% ^{12}C and 90% ^{16}O (by mass). The authors find nonradial and radial instability strips for each composition caused by the partial ionization of carbon or oxygen or both. The objective is to find the cause of the observed pulsations of PG 1159-035, a hot, evolved star with $T_{\text{eff}} \geq 10^5 \text{ K}$. While this star may be too hot to lie within any of our new instability strips, the closest agreement comes from models with significant amounts of ^{16}O near the stellar surface. If correct, this result implies that helium burning in evolved stars produces much more ^{16}O than heretofore believed. (20 refs.)
- 78923 Photometry of the post T Tauri star HD 36705.** S.M.Rucinski (Max-Planck-Institut für Astrophysik, München, Germany). *Astron. & Astrophys. Suppl. Ser. (France)*, vol.52, no.2, p.281-7 (May 1983). Two series of observations in the *uvby* and *UBVRI* systems separated by 3 months are presented. The short rotational period of 0.514 days is confirmed, the light curves show high level of variability on time scales ranging from a few days to months. The mean values of the (*b-y*) or (*B-V*) colours are consistent with a K1 spectrum but other indices suggest a flatter spectral distribution than in normal stars. Variations in photometric indices correlate poorly with those in brightness suggesting that in addition to spots the chromospheric sources might contribute significantly to the observed variability. The young age inferred from the short period and the presence of lithium in the atmosphere indicate a possible similarity to the fast rotating K-type stars in the Pleiades cluster. (19 refs.)
- 78924 New optical positions and proper motions of late type stars associated with SiO masers.** G.Soulie, A.Baudry (Obs., Univ. de Bordeaux, Floirac, France). *Astron. & Astrophys. Suppl. Ser. (France)*, vol.52, no.2, p.299-309 (May 1983). The 33 cm astrophotograph of the Bordeaux Observatory has been used to derive with respect to AGK3 reference stars, accurate positions of late type variable stars associated with strong SiO maser emission. It is suggested that selected maser stars can be used to link the HIPPARCOS system and the VLBI extragalactic reference frame. The proper motions of the program (SiO) and reference stars are derived and, for the program stars, are compared to the McCormick catalog of proper motions. (28 refs.)
- 78925 Additional variable stars in the SRS catalogue.** C.Lopez (Obs. Felix Aguilar, San Juan, Argentina). *Inf. Bull. Variable Stars (Hungary)*, no.2328, 1 pp. (6 May 1983). A new cross index between 29 known variables and Southern Reference Stars is presented. (1 ref.)
- 78926 The period variations of UX Dra.** M.Vetevnik (Dept. of Astron., Brno Univ., Brno, Czechoslovakia). *Inf. Bull. Variable Stars (Hungary)*, no.2329, 2 pp. (6 May 1983). New times of minimum light of the carbon star UX Dra are derived from the three colour photoelectric observations made at Brno Observatory and from the observations made by Dzervitis et al. (1973). The lengthening of the period is discussed. (2 refs.)
- 78927 HD 87072: a new, bright, very small amplitude, short period Cepheid.** O.J.Eggen (Cerro Tololo Inter-American Obs., La Serena, Chile). *Inf. Bull. Variable Stars (Hungary)*, no.2331, 3 pp. (9 May 1983). HD 87072 is classified F8 Ib/II by Houk and Cowley (1975) and was included in a program of intermediate band and H β observations of F-type supergiants. Single, one-per-night, observations over a two-year span are listed. The light elements, $\text{Max} = \text{JD } 2445033.630 + 2.063515^d$ best satisfy these results and the resulting light and colour curves are shown. An alternative period of 0.6737^d doubles the dispersion of the individual observations. (1 ref.)
- 78928 Additional historical brightenings of VY Aquarii?.** G.A.Richter (Akad. der Wissenschaften, Sonneberg, Germany). *Inf. Bull. Variable Stars (Hungary)*, no.2332, 3 pp. (11 May 1983). Reports the results of examining more than 1000 plates of the Sonneberg sky patrol. Further investigation by authors having access to other plate archives is invited. (3 refs.)
- 78929 On the changes in the light curves of long period variables.** J.Mergentaler (Inst. Astron. Uniwersytetu Wrocławskiego, Wrocław, Poland). *Postępy Astron. (Poland)*, vol.30, no.3-4, p.315-19 (July-Dec. 1982). In Polish. [received: April 1983] Shape differences between even and odd light curves of long period variables are discussed. The distribution of occurrence of the effect is discussed. Deviations from the mean of the light increase time for RW Sgr and X Gem are given. (2 refs.)
- 78930 Thirteen-color photometry of sixteen variable Be stars. I. Photometry.** M.Alvarez, W.J.Schuster (Inst. de Astron., Univ. Nacional Autonoma de Mexico, Mexico City, Mexico). *Rev. Mex. Astron. & Astrofis. (Mexico)*, vol.5, no.3, p.173-8 (July 1982). [received: April 1983] Presents thirteen-color photometry of 16 variable Be stars observed at the Observatorio Astronomico Nacional in San Pedro Martir in Baja California. The data cover the years 1977 to 1979, and the authors include earlier measurements of Johnson and Mitchell from 1965 to 1968 that have been corrected in order to have a homogeneous set of data. 97.60B Supernovae

78931 Supernova in NGC 4753. C.J.Peterson, R.Evans. *I.A.U. Circ. (USA)*, no.3814, 1 pp. (20 May 1983).

Reports UVB photometry of the supernova in NGC 4753 on 1983 April 10 to 11 and April 17 to 19. The data suggest photometric behaviour typical of a Type I supernova. It is also reported that visual observations suggest that the supernova was 0.2 mag. brighter on April 10 than on April 6 and 9. (1 ref.)

78932 Supernova in NGC 3106. Yu.V.Terebizh.

I.A.U. Circ. (USA), no.3815, 1 pp. (24 May 1983).

Reports the discovery of a supernova 11" east and 12" south of the nucleus. The photographic magnitude was 16.0 on 1983 April 8. (no refs.)

Detection of gravitational collapse See Entry 78818

Ring ejection in Type II supernovae: IE 0102.2-7219 in the Small Magellanic Cloud See Entry 78976

97.60G Pulsars

78933 An attempt to resolve pulsar magnetospheres using interstellar scintillations. J.M.Cordes (Cornell Univ., Ithaca, NY, USA), J.M.Weisberg, V.Boriakoff.

Astrophys. J. (USA), vol.268, no.1, pt.1, p.370-80 (1 May 1983).

Interstellar scintillations of separate pulse components were measured as a test for whether the corresponding emission regions are spatially separated when radiation toward an observer. Pulse components scintillate identically within the errors, implying that the emission regions have transverse separations $\leq 10^3$ km. In polar cap models, such separations correspond to a limit on emission altitude of 6% of the light-cylinder radius for PSR 0525+21. In light cylinder models, the limits require that nonazimuthal velocities of the emission regions must be identified to within $\Delta v/v \leq 0.06$ and must be within 3° of the radial direction. (26 refs.)

78934 Is the millisecond pulsar formed from coalescence of a close neutron-star binary? H.F.Henrichs, E.P.J.van den Heuvel (Astron. Inst., Univ. of Amsterdam, Amsterdam, Netherlands).

Nature (GB), vol.303, no.5914, p.213-16 (19 May 1983).

The combination of short pulse period and abnormally weak surface dipole magnetic-field strength of PSR 1937+214 has led to the suggestion that it is an old neutron star that was spun up by accretion in a binary system. In this article the authors point out the difficulties with such a model: massive binaries are unlikely to live sufficiently long to allow the required amount of spin-up matter ($\geq 0.1 M_\odot$) to be accreted; in low-mass binaries the companion star is still expected to be present. It is argued that a likely alternative is: formation by coalescence of two neutron stars that formed a close binary such as PSR1913+16. These (inevitable) events may occur in the galaxy at a rate $\sim 10^{-4} \text{ yr}^{-1}$, and provide a natural explanation of the millisecond rotation period. (39 refs.)

78935 Direct observational upper limit to gravitational radiation from millisecond pulsar PSR 1937+214. J.Hough (Dept. of Natural Philosophy, Glasgow Univ., Glasgow, Scotland), R.W.P.Drever, H.Ward, A.J.Munley, G.P.Newton, B.J.Meers, S.Hoggan, G.A.Kerr.

Nature (GB), vol.303, no.5914, p.216-17 (19 May 1983).

The millisecond pulsar PSR 1937+214 has such a high rotational rate, 642 Hz, that any significant quadrupole moment not aligned with the spin axis could lead to a large flux of gravitational radiation. Although recently reported slowdown rates suggest an energy loss corresponding to a currently unobservable level of gravitational radiation, existing evidence may not completely rule out all possibilities for production of detectable gravitational waves. For example, continuing accretion might provide additional energy for gravitational radiation: the authors describe a search that has set an upper limit to gravitational wave amplitude at twice the pulsar rotation frequency. (6 refs.)

78936 A radio pulsar in the Large Magellanic Cloud. P.M.McCulloch, P.A.Hamilton (Dept. of Phys., Univ. of Tasmania, Hobart, Tasmania, Australia), J.G.Ables, A.J.Hunt.

Nature (GB), vol.303, no.5915, p.307-8 (26 May 1983).

A high-sensitivity search for pulsars in the Large Magellanic Cloud is in progress using the 64-m radio telescope at Parkes, New South Wales. About 7 square degrees have yielded the first extragalactic radio pulsar, PSR 0529-66, and several promising but weaker candidates which require further observations. The new pulsar has a period of 0.9757141 s, a dispersion measure of $125 \text{ cm}^{-3} \text{ pc}$, and a mean flux density of 1.4 mJy at 645 MHz. Its position is RA=05 h 29 min 30 \pm 1 s, dec=-66 $^\circ$ 57' \pm 8' (1950.0). (4 refs.)

78937 Oblateness effects on the spin-down of fast pulsars. R.Cowsik, P.Ghosh, M.A.Melvin (Tata Inst. of Fundamental Res., Bombay, India).

Nature (GB), vol.303, no.5915, p.308-10 (26 May 1983).

Assuming that the very rapidly rotating pulsar PSR 1937+214 is a fast-rotating superdense fluid, it is shown that the increase in the moment of inertia and in the gravitational self-energy of the spheroid due to its oblateness lead to substantial differences in the time evolution of the pulsar from that predicted by the standard models. Careful observations of its \dot{P} , \ddot{P} and its spectrum can put constraints on the properties of neutron star matter. Even with the existing observation of $\dot{P}=1.56 \text{ ms}$, considerations of dynamical stability of the rapidly rotating neutron star yield a lower limit $\dot{P} > 1.7 \times 10^{-14} \text{ g cm}^{-3}$ for the mean stellar density. (12 refs.)

78938 Abnormal neutron stars with abnormal protons. III. Metastable stars and phase transition. Qu Qin-yue, Wang Zhen-ru (Astron. Dept., Nanjing Univ., Nanjing, China).

Commun. Theor. Phys. (China), vol.1, no.4, p.531-4 (1982).

For pt.II see ibid., vol.1, no.3, p.371-7 (1982). The abnormal neutron stars containing abnormal protons are compared with the normal neutron stars in

order to determine which of them are metastable and the phase transition between metastable and stable stars is discussed. (5 refs.)

78939 Some characteristics of a rapidly rotating magnetized neutron star.

A.Ray, S.M.Chitre (Tata Inst. of Fundamental Res., Bombay, India).

Nature (GB), vol.303, no.5916, p.409-10 (2 June 1983).

The 1.5-ms pulsed radio source PSR 1937+214 could be close to the onset of rotational instabilities if it is envisaged to be a rotating neutron star which gives interesting lower limits for neutron star masses. The authors examine the implications of polar gap models for such a rapidly rotating magnetic neutron star. It appears, on the basis of such models, that a higher fraction of high-frequency microwave radiation compared with the Crab pulsar is an expected result. On the other hand, the outer gap discharge models invoked for longer period pulsars yield a large amount of high-energy radiation which is not observed. The high-energy cutoff in the γ -ray region evaluated from assumed values of the magnetic field inside the light cylinder will be around 1000 GeV. (18 refs.)

97.80 BINARY AND MULTIPLE STARS

(inc. extrasolar planetary systems)

78941 Spectroscopy of V711 Tauri (=HR 1099): fundamental properties and evidence for starspots. F.C.Fekel, Jr. (Lab. for Astron. & Solar Phys., Goddard Space Flight Center, Greenbelt, MD, USA).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.274-81 (1 May 1983).

As a result of continued spectroscopic observations, new orbital elements are determined for the bright RS CVn-type system V711 Tau (=HR 1099). The spectroscopic period is refined to $2.83774^d \pm 0.00001^d$. From the estimated age of the system and evolutionary considerations, the inclination of the system is $33^\circ \pm 2^\circ$. This inclination, combined with the orbital elements and the $v \sin i$ for each component, results in the masses, radii, and equatorial rotational velocities for Aa and Ab. Evolutionary models suggest that mass transfer may begin in $7-8 \times 10^7$ yr. High signal-to-noise Reticon observations at red wavelengths show substantial differences in rotational velocity and line strength between the two components, as well as asymmetries in all absorption lines of Aa, the more massive, active, cooler star. These asymmetries are correlated with the photometric variations and move across the line profiles with time. They are the result of starspot regions rotating in and out of view. The detection of such asymmetries at times of low photometric amplitude in 1981 is evidence for a redistribution of spots rather than a substantial change in activity level. (56 refs.)

78942 X-ray spectra and light curves of accreting magnetic degenerate dwarfs. J.Imamura (Dept. of Astron., Univ. of Virginia, Charlottesville, VA, USA), R.H.Durisen.

Astrophys. J. (USA), vol.268, no.1, pt.1, p.291-308 (1 May 1983).

Reports detailed calculations of the X-ray spectra and X-ray light curves of accreting magnetic $1 M_\odot$ degenerate dwarfs. The authors use accretion funnel models in which plasma flows toward the dwarf along dipole magnetic field lines and accretes onto a small cap at the dwarf's magnetic pole of area $4\pi R_*^2 f$, where R_* is the stellar radius and $f \leq 1$. The X-ray spectra of weakly magnetic degenerate dwarfs are qualitatively similar to the spectra of non-magnetic dwarfs. The majority of the X-rays escape in directions perpendicular to the field lines. This has two effects: (1) For magnetic and nonmagnetic models with equivalent accretion rates per square centimeter, the emergent photons in the magnetic case suffer fewer scatterings than those in the nonmagnetic case and thus show less energy degradation. The shapes of the light curves are sensitive to f and L_* to the inclination of the magnetic field axis to the dwarf's rotation axis, and to the viewing angle of the dwarf. Thus, observed X-ray light curves can be used to constrain the physical characteristics and geometry of the accreting degenerate dwarf. (32 refs.)

78943 Approximations to the radii of Roche lobes. P.P.Eggleton (Inst. of Astron., Univ. of Cambridge, Cambridge, England).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.368-9 (1 May 1983).

Effective radii of Roche lobes are computed and compared with the results of Kopal (1959) and Pacynski (1971). A convenient approximation is given, whose derivative is smooth and fairly accurate. (2 refs.)

78944 Detection of 2×10^{15} to 2×10^{16} eV gamma-rays from Cygnus X-3. M.Samorski, W.Stamm (Inst. für Reine und Angewandte Kernphys., Univ. of Kiel, Kiel, Germany).

Astrophys. J. Lett. Ed. (USA), vol.268, no.1, pt.1, p.L17-21 (1 May 1983).

The experimental data of the extensive air shower experiment at Kiel have been analyzed with respect to showers from Cyg X-3. The measurements have been performed from 1976 March 18 to 1980 January 7 with an angular resolution of 1° . The effective on-source observation time was 3838 hr at a sensitive area of 2.800 m^2 . The time-averaged analysis gives a 4.4σ excess of showers from the direction $\delta = 40.9^\circ \pm 1.5^\circ$ and $\alpha = 307.8^\circ \pm 2.0^\circ$. In addition, the excess showers show the typical 4.8 hr modulation, with a signal-to-noise ratio of 9 in the phase maximum. The time-averaged integral γ -ray flux is derived. It corresponds to a luminosity of $6 \times 10^{36} \text{ ergs s}^{-1}$ in the energy region $2 \times 10^{15} \text{ eV}$ to $2 \times 10^{16} \text{ eV}$. This is the first experimental evidence for a clearly identified γ -ray point source emitting at energies greater than 10^{15} eV . (19 refs.)

78945 VLBI observations of a radio flare of Circinus X-1. R.A.Preston, D.D.Morabito, A.E.Wehrle (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA), D.L.Jauncey, M.J.Batty, R.F.Haynes, A.E.Wright, G.D.Nicolson.

Astrophys. J. Lett. Ed. (USA), vol.268, no.1, pt.2, p.L23-6 (1 May 1983). A strong (~ 1.2 Jy) radio flare of the binary star system Circinus X-1 was observed with VLBI at three southern hemisphere observatories. The 2.3 GHz observations were made from 1980 April 22 to 28 and commenced 1 day prior to the flare outburst. Throughout the observation period, the flaring component of the radio source had an angular size, θ , in the range of $0.0015'' \leq \theta \leq 0.015''$. This is equivalent to a linear size of 15-150 AU at the 10 kpc distance of Circinus X-1. The quiescent component of the radio source observed prior to the flare was found to have an angular size of $\geq 0.2''$. This is equivalent to a linear size of ≥ 2000 AU at 10 kpc. Hence, the quiescent radio emission comes from a region much larger than that proposed in recent models for Circinus X-1. The quiescent component appears to be variable on a time scale of years and is probably fueled by the Circinus X-1 binary system. (15 refs.)

78946 Photographic observations of visual double stars. E.van Albada-van Dien (Astron. Inst., Univ. of Amsterdam, Amsterdam, Netherlands).

Astron. & Astrophys. Suppl. Ser. (France), vol.52, no.2, p.193-202 (May 1983). Presents the results of photographic observations of 199 visual double stars, obtained at the Bosscha Observatory at Lembang, Indonesia, in the years 1958-1975 (with one 1953 plate). The material comprises 708 plates with an average of 37 images measured per plate. (3 refs.)

78947 TV Cassiopeiae in the Utrecht Photometric System. A.C.de Landt-sheer (Astron. Inst., Rijksuniv. Utrecht, Utrecht, Netherlands).

Astron. & Astrophys. Suppl. Ser. (France), vol.52, no.2, p.213-36 (May 1983).

Four UPS light curves of TV Cas are presented. An instantaneous period analysis of these curves and previously published data reveals erratic relative period changes of over $10E-6$ a year. The secondary minimum appears to be at phase 0.502. Light curve analysis indicates that the cool component fills its Roche lobe and is of spectral type G5-G9IV. Roche lobe overflow is not sufficient to explain the observed secular decrease of the period. Other mechanisms may be found in the chromospheric activity of the cool component. This activity is suggested by the observed small variations in the light curves with a characteristic period of about a year. (55 refs.)

78948 Contribution to the study of F, G, K, M type binaries. I. Orbital elements of the double lined spectroscopic binaries HD 47415 and HD 210763. R.Nadal, J.M.Carquillat, A.Pedoussaut, N.Ginestet (Obs. de Pic-du-Midi et de Toulouse, Toulouse, France).

Astron. & Astrophys. Suppl. Ser. (France), vol.52, no.2, p.293-7 (May 1983). In French.

The spectroscopic binaries HD 47415 and HD 210763 were observed at the Observatoire de Haute-Provence in order to determine their spectrographic orbits. The orbital elements obtained are presented. For these two binaries, the mass-ratio near 0.8 and the primary spectral type (F8 IV and F5 IV respectively) indicates a main sequence F-type secondary. The two systems appear to be detached and eclipses are possible for HD 210763. (11 refs.)

78949 Lightcurve synthesis of the semi-detached binaries LT Her, WX Eri, AW Cam. G.Russo, L.Milano (Capodimonte Astron. Obs., Napoli, Italy).

Astron. & Astrophys. Suppl. Ser. (France), vol.52, no.2, p.311-16 (May 1983).

Analyzes, by means of a Roche-model-based method for lightcurve synthesis, the photometric observations of the eclipsing binaries LT Her, WX Eri, AW Cam. All systems are found to be semi-detached, with a main sequence primary and a lobe filling evolved secondary. (21 refs.)

78950 Four-colour photometry of eclipsing binaries. XV B. Light curves of V Puppis. J.V.Clausen, B.Nordstrom, B.Reipurth (Copenhagen Univ. Obs., Tollose, Denmark).

Astron. & Astrophys. Suppl. Ser. (France), vol.52, no.2, p.323-31 (May 1983).

UBV light curves of the semi-detached early B-type eclipsing binary V Puppis are presented. (2 refs.)

78951 Analysis of the UVB light curves of TT Hydrae by Kopal's frequency domain method. J.Koul, K.D.Abhyanekar (Centre of Advanced Study in Astron., Osmania Univ., Hyderabad, India).

J. Astrophys. & Astron. (India), vol.3, no.2, p.93-9 (June 1982). [received: June 1983]

The light curves of the totally eclipsing system TT Hya in UVB colours observed by Kulkarni and Abhyankar (1981) during 1973-77 are analysed by Kopal's (1979) frequency domain method with slight modification. The authors find r_p (primary) = 0.104 ± 0.005 , r_s (secondary) = 0.215 ± 0.008 and $i = 89^\circ \pm 1^\circ$. The value of r_s obtained is smaller than that determined earlier by Kulkarni and Abhyankar by the method of Russell and Merrill; this confirms the undersized nature of the secondary component. The ultraviolet colour excess of the secondary is also confirmed. (9 refs.)

78952 Spectroscopic binaries near the North Galactic Pole. IV. HD 120803. R.F.Griffin (Obs., Cambridge Univ., Cambridge, England).

J. Astrophys. & Astron. (India), vol.3, no.2, p.101-5 (June 1982). [received: June 1983]

For pt.III see *ibid.*, vol.3, no.1, p.1-4 (1982). Photoelectric radial-velocity measurements show that HD 120803 is a spectroscopic binary with a rather eccentric orbit and a period of 700 days. Early DDO photographic observations, published individually by the author for the first time, fit the orbit well. (7 refs.)

78953 Spectroscopic binaries near the North Galactic Pole. V. HD 117064. R.F.Griffin (Obs., Cambridge Univ., Cambridge, England).

J. Astrophys. & Astron. (India), vol.3, no.2, p.107-9 (June 1982). [received: June 1983]

For pt.IV see *ibid.*, vol.3, no.2, p.101-5 (1982). Photoelectric radial-velocity measurements, which in 1971 showed HD 117064 to be a spectroscopic binary, have been continued and now permit the derivation of an eccentric orbit with a period of 6.08 years. (7 refs.)

78954 On the period of EG Cephei. U.Hopp (Inst. fur Astron., Technische Univ., Berlin, Germany), E.H.Geyer, F.T.Lentes.

Inf. Bull. Variable Stars (Hungary), no.2327, 4 pp. (4 May 1983).

The authors have reobserved this β Lyrae-type eclipsing binary in the nights of Sept. 1/2, 2/3, 3/4, 1980 with a double beam photometer attached at the Nasmyth focus of the 106 cm Cassegrain telescope of Hoher List Observatory. A total of 307 U, 614 B and 614 V-observations were obtained. One time instant for the primary and two time instants for the secondary minima are derived by the Pogson method. A period of 0.54462159^d is indicated and shown to be constant during 1959-80 to within 9×10^{-5} day. (8 refs.)

78955 Radial velocity measurements of α Pyx and ζ Cma. C.Sterken, D.Vander Linden (Astrophys. Inst., Vrije Univ., Brussels, Belgium).

Inf. Bull. Variable Stars (Hungary), no.2330, 4 pp. (9 May 1983). In 1980 a spectroscopic monitoring of bright southern B stars using the 90 cm telescope of Manuel Foster Observatory, Santiago de Chile, was started. The programme consists of systematic observations of southern early-type B stars which are too bright to be observed photometrically. During the first months of operation a one-prism spectrograph with a dispersion of 36 \AA/mm at H γ was used. ζ Canis Majoris (HR 2282) was monitored during 4 nights in December 1980 and January 1981 and α Pyxidis (HR 3468) during 5 nights in December 1980 and March 1981. (4 refs.)

78956 Infrared variability of HR 7275. M.Zeilik, R.Elston, G.Henson, P.Smith (Dept. of Phys. & Astron., Univ. of New Mexico, Albuquerque, NM, USA).

Inf. Bull. Variable Stars (Hungary), no.2333, 4 pp. (13 May 1983).

Reports infrared photometry of the long-period, non-eclipsing system HR 7275 that clearly shows phase-dependent infrared light curves. All observations were carried out with the 1.3-meter telescope at Kitt Peak National Observatory during the day. The observations spanned December 1980 to February 1981; most were clustered in January 1981. (4 refs.)

78957 New eclipsing supergiant 22 Vul. S.B.Parsons (Lab. for Astron. & Solar Phys., Goddard Space Flight Center, Greenbelt, MD, USA), T.B.Ake.

Inf. Bull. Variable Stars (Hungary), no.2334, 1 pp. (13 May 1983).

An eclipse of 22 Vul (HD 192713, V=5.15), spectral type G3 Ib-II, was observed on 17 April 1983 during IUE observations from 18^h to 21^h UT. The star is a single-lined spectroscopic binary with period 249.1 days. (no refs.)

78958 XY Leo and the star BD+18°2304. D.R.Faulkner, D.H.Grossoehme (Astron. Dept., Indiana Univ., Bloomington, IN, USA).

Inf. Bull. Variable Stars (Hungary), no.2335, 2 pp. (16 May 1983).

De Carlo and Sabatini (1967) may have observed XY Leo (BD+18°2307) and misidentified it as BD+18°2304. To test this hypothesis both XY Leo and BD+18°2304 were observed on five nights during the spring of 1983 using the 41 cm reflector of the Morgan-Monroe Station of the Goethe Link Observatory. Johnson UVB filters were used with a 1P21 photomultiplier tube cooled with dry ice. The comparison star used was BD+18°2306. The complete light curve of XY Leo was observed, thus if BD+18°2304 is a variable having a similar period, variations in its brightness should have been apparent. However, the magnitude of BD+18°2304 as determined with each filter remained constant within 0.05^m . It is concluded that BD+18°2304 is not an eclipsing binary and that De Carlo and Sabatini unknowingly observed XY Leo. (3 refs.)

78959 On radial velocity and the motion of spectroscopic binary stellar systems. V.G.Shkodrov, B.Z.Kovachev (Astron. Obs., Bulgarian Acad. of Sci., Sofia, Bulgaria).

C.R. Acad. Bulg. Sci. (Bulgaria), vol.36, no.1, p.11-13 (1983).

When the components of a close binary stellar system move in a plan tangential to the celestial sphere τ , the radial velocity γ is considered to be zero. On the other hand, in celestial mechanics it is well known that, when two bodies move around their mass centre, oscillations are observed in the inclination of the orbital plane. These are caused by the non-uniform distribution of the matter in the two components. Consequently the oscillations, if they do exist, must be the cause of the non-zero radial velocities. The effect of the oscillation of the orbital plane around τ on the radial velocity γ is formulated theoretically. (6 refs.)

78960 The orbit of visual binary ADS 4396=A 2657. R.R.de Freitas Mourao, O.C.Tavares, M.R.Nunes (Obs. Nacional, Rio de Janeiro, Brazil).

Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.3, p.135-6 (July 1982). [received: April 1983]

The physical and orbital elements of the binary star ADS 4396=A 2657 are determined. The reductions were performed on the IBM 370/145 computer at the LCC-Laboratorio de Computacao Cientifica do CNPq (Conselho Nacional de Desenvolvimento Cientifico e Tecnologico). (2 refs.)

78961 Binary-single star scattering. I. Numerical experiments for equal masses. P.Hut, J.N.Bahcall (Inst. for Advanced Study, Princeton, NJ, USA).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.319-41 (1 May 1983).

More than a million numerical orbit calculations have been carried out for binary-single star gravitational scattering in the case of equal masses. For the first time a Monte Carlo sampling has been possible over the full dimen-

sionalities of phase space without having to make any assumptions about dependence on orientation, phase angles, or impact parameter. Total cross sections are obtained for ionization, exchange, and resonance scattering and their detailed dependence on incoming velocity is plotted for initial binary orbits of zero, moderate, and extreme eccentricity. (26 refs.)

78962 Binary-single star scattering. II. Analytic approximations for high velocity. P.Hut (Inst. for Advanced Study, Princeton, NJ, USA). *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.342-55 (1 May 1983).

For pt.1 see *ibid.*, vol.268, no.1, pt.1, p.319-41 (1983). Differential cross sections are derived for binary-single star gravitational scattering at high incoming velocity as a function of the amount of energy exchange, in the impulsive approximation. The full dependence of the differential cross sections on the initial orbital eccentricity of the binary is given for flyby and exchange scattering. Total cross sections for ionization and exchange scattering are presented and shown to be independent of binary eccentricity. The results are compared with detailed balance relations, previous analytic approximations by Heggie (1975), and numerical calculations by Hut and Bahcall (1983). (4 refs.)

78963 Analysis of box orbits in a triaxial galaxy. M.Vietri, M.Schwarzschild (Princeton Univ. Obs., Princeton, NJ, USA).

Astrophys. J. (USA), vol.269, no.2, pt.1, p.487-99 (15 June 1983). Binney and Spergel (1982) have pointed out that in a triaxial potential, box orbits—indeed all regular orbits—are quasi-periodic. This strong feature of regular orbits is exploited to derive a short development for box orbits in the equatorial plane of a triaxial potential. For the zero order terms the closed orbit was chosen which lies along the long (X) axis in the stationary case (no figure rotation) or near this axis in the case with figure rotation. The period of this orbit provides the first frequency. The first order terms were taken to be the linear perturbation of this closed orbit, which through the corresponding Floquet equations provide the second frequency. On the second order terms only those which directly improve the reproduction of the shape of the orbit have been retained; those providing corrections to the frequencies have been ignored. In the resulting development each term is a product of one factor periodic in the first frequency and another factor harmonic in the second frequency. This development to incomplete second order was applied to a number of box orbits with a radial extent of about 10 core radii. (6 refs.)

78964 Spectroscopic analysis of dwarf and subgiant stars in 47 Tucanae. R.A.Bell (Nat. Sci. Foundation, Washington, DC, USA), J.E.Hesser, R.D.Cannon.

Astrophys. J. (USA), vol.269, no.2, pt.1, p.580-91 (15 June 1983). Spectra have been obtained for 11 dwarfs ($B - 18.2$ mag) and five brighter stars ($B - 16$ mag) in NGC 104 (47 Tuc, C 0021-723). A range of CN strengths is observed among subgiant and dwarf stars of otherwise very similar spectra. The spectroscopic results are combined with photometric data to argue that some, if not all, of the dwarfs have the same temperature. Spectrum synthesis calculations are then used to infer that the observed range of CN strengths could be produced by a star-to-star range of nitrogen abundances of ~ 5 . This result is in accord with a previous analysis based upon much lower resolution data. The range inferred is similar to that required to explain observations of high evolved stars in 47 Tuc. (31 refs.)

78965 V-photometry of bright stars in central region of globular cluster M5. N.M.Spassova (Astron. Obs., Bulgarian Acad. of Sci., Sofia, Bulgaria). *C.R. Acad. Bulg. Sci. (Bulgaria)*, vol.36, no.1, p.15-18 (1983).

The results are presented of photometry of the nucleus of globular cluster M5. The V-magnitudes of the bright red stars in the cluster's central part were obtained on three plates taken with the 65-cm Pulkovsky refractor. The V-system was realized by means of Kodak OaD plates + filter JS 16, while the cluster's central part was divided by 3-min and 4-min exposures. With the given scale (19.81" per mm) and the available photomaterial, reliable photometry in the central part could be obtained only for stars brighter than $V = 13.21$. The plates were measured on an iris microphotometer in the Pulkovsky observatory. (10 refs.)

98.40 INTERSTELLAR MATTER; AND NEBULAE

78966 An energetic, bisymmetrically expanding H I remnant. F.J.Lockman, B.L.Ganzel (Nat. Radio Astron. Obs., Charlottesville, VA, USA).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.117-22 (1 May 1983). There is a unique H I system in Monoceros that contains two arcs of gas, expanding bisymmetrically at 26 km s $^{-1}$, apparently moving through the interstellar medium like solid bodies. One of them is interacting with a large H I cloud. The total mass in moving atomic gas is $2.4 \times 10^5 M_{\odot}$, with a kinetic energy of 1.6×10^{50} ergs. The arcs are ~ 5 kpc from the Sun and overlap to form a ring with a projected diameter of ~ 200 pc. The kinetic temperature in some parts of the moving features is less than 350K. The singular morphology and kinematics of this system makes it unlikely that it resulted from a spherical or circularly symmetric explosion. There are also problems in accounting for the energy and momentum of the moving gas, the details of the geometry, and the density ratio between the moving gas and the cloud into which it is apparently moving. (23 refs.)

78967 An extensive galactic search for conformer II glycine. L.E.Snyder (Univ. of Illinois, Urbana, IL, USA), J.M.Hollis, R.D.Suenram, F.J.Lovas, L.W.Brown, D.Buhl.

Astrophys. J. (USA), vol.268, no.1, pt.1, p.123-8 (1 May 1983). Conducts the most extensive galactic search reported to date for conformer II glycine, a higher energy form of the simplest amino acid. The search utilized four glycine transitions at centimeter wavelengths and 21 at millimeter wavelengths to observe 18 galactic molecular sources and one comet. No conformer II glycine lines were detected and measurements of representative sources were used to compute upper limits on total column densities. Several unidentified lines were detected and are reported with some suggested possible identifications. (19 refs.)

78968 Optical studies of Cassiopeia A VI. Observations during the period 1976-80. S.van den Bergh (Dominion Astrophys. Obs., Herzberg Inst. of Astrophys., Victoria, BC, Canada), K.W.Kamper.

Astrophys. J. (USA), vol.268, no.1, pt.1, p.129-33 (1 May 1983). For pt.V see *Astrophys. J. Suppl. Ser.*, vol.32, no.2, p.351-66 (1976). Previously published observations of the fast moving knots in Cas A obtained between 1951 and 1975 have been supplemented by eight new Hale 5 m

prime focus plates taken in 1976, 1977, and 1980. Combining new observations of 46 long-lived knots with previously published data yields an explosion date $T_0 = 1658 \pm 3$. No significant deceleration was detected in 36 knots that have been observed for at least 20 years. New proper motions are also given for three quasi-stationary flocculi. Attention is drawn to a cluster of exceedingly faint flocculi located outside the Cas A radio shell. One of these objects became visible almost simultaneously at optical and at radio wavelengths. (10 refs.)

78969 High-velocity, asymmetric Doppler shifts of the X-ray emission lines of Cassiopeia A. T.H.Markert, C.R.Canizares, G.W.Clark (Dept. of Phys., MIT, Cambridge, MA, USA), P.F.Winkler.

Astrophys. J. (USA), vol.268, no.1, pt.1, p.134-44 (1 May 1983). Performs high spectral resolution measurements of several X-ray emission lines from the young supernova remnant Cassiopeia A. The spectrum of the X-ray emitting gas in the northwest half of Cas A is redshifted with respect to that in the southeast. The authors interpret this phenomenon. The measurements demonstrate directly that the bulk of the gas making up Cas A is moving at high velocities. The authors construct a simple geometric model consistent with the general features of the X-ray spectrum and image of Cas A. The data require an expansion velocity in excess of 2000 km s $^{-1}$. The high velocities required for the X-ray matter imply that the relatively cool X-ray emitting material observed is most probably supernova ejecta which has been heated by a reverse shock wave. The X-ray and optical data are most compatible with the view that Cas A is still in its free-expansion stage. The authors find the X-ray emitting mass and the kinetic energy. (41 refs.)

78970 The effects of mass and metallicity upon planetary nebula formation. K.A.Papp (Dept. of Phys., Univ. of Waterloo, Waterloo, Ontario, Canada), C.R.Purton, S.Kwok.

Astrophys. J. (USA), vol.268, no.1, pt.1, p.145-54 (1 May 1983). Constructs a parameterized function which describes the possible dependence of planetary nebula formation upon metal abundance and stellar mass. Data on galaxies in the Local Group compared with predictions made from the parameterized function indicate that heavy element abundance is the principal agent influencing the formation of planetary nebulae; stars which are rich in heavy elements are the progenitors of planetary nebulae. The analysis, when compared with the observations, argues for a modest degree of pre-enrichment in a few of the sample galaxies. The heavy elements dependence of planetary nebula formation also accounts for the deficit of planetary nebulae in the nuclei of NGC 221 and NGC 224, and in the bulge of our Galaxy. (70 refs.)

78971 X-ray sources in molecular clouds. S.Lepp, R.McCray (Joint Inst. for Lab. Astrophys., Univ. of Colorado, Boulder, CO, USA).

Astrophys. J. (USA), vol.269, no.2, pt.1, p.560-7 (15 June 1983). Models are calculated for the structure and infrared line emission from a dense interstellar gas cloud containing a compact X-ray source. For constant gas pressure models, the resulting structure consists of nested spherical shells containing, respectively, coronal gas at $T > 10^6$ K, and H II region with $T \sim 10^4$ K, an H I region with $T \sim 8000$ K, and finally an H $_2$ region with $T < 5000$ K. Scaling laws are given for the locations of the transitions. Approximately 10% of the X-ray luminosity absorbed in the H $_2$ region is converted into infrared emission lines that may be observable. Line ratios are presented. (51 refs.)

78972 A rotating protocluster in W58:HCO $^+$ aperture synthesis maps. S.N.Vogel, W.J.Welch (Radio Astron. Lab., Univ. of California, Berkeley, CA, USA).

Astrophys. J. (USA), vol.269, no.2, pt.1, p.568-79 (15 June 1983). Maps 89.2 GHz HCO $^+$ ($J = 1-0$) emission from a molecular cloud near K3-50. The cloud, which the authors call W58 (HCO $^+$), has $T > 40$ K, $n(\text{H}_2) > 10^5$ cm $^{-3}$, and $M \approx 2000 M_{\odot}$. The maps show a systematic velocity gradient of 8 km s $^{-1}$ pc $^{-1}$ extending over more than 1 pc. The velocity gradient is best fitted by rotation of the cloud with velocity increasing outwards and is consistent with solid body rotation. A plausible history is discussed. In all likelihood W58 (HCO $^+$) is the precursor to an open cluster or association, and fragments within the cloud are now forming stars. The cloud rotates significantly faster than open clusters and is much denser. However, the authors find that the eventual expansion of the cluster leads to a rotational velocity and mass density in accord with observations of open clusters. The effect of expansion on rotation of open clusters is considered. (35 refs.)

78973 The binary central star of the planetary nebula LT-5. W.A.Feibelman (Lab. for Astron. & Solar Phys., NASA Goddard Space Flight Center, Greenbelt, MD, USA), J.B.Kaler.

Astrophys. J. (USA), vol.269, no.2, pt.1, p.592-5 (15 June 1983). The authors found with the IUE that the true central star of the giant planetary Longmore-Tritton 5 ($339 + 88^\circ 1$) is a binary companion to the G5 star SAO 82570. The slope of the energy distribution curve indicates that the star may be one of the hottest known. The Mg II doublet associated with the G star is very strong, consistent with the existence of a close binary companion. (13 refs.)

78974 Infrared observations of OB star formation in NGC 6334. P.M.Harvey, I.Gatley (Astron. Dept., Univ. of Texas, Austin, TX, USA), I.Gatley.

Astrophys. J. (USA), vol.269, no.2, pt.1, p.613-24 (15 June 1983). Infrared photometry and maps from 2 to 100 μ m are presented for three of the principal far-infrared sources in NGC 6334. Each region is powered by two or more very young stars. The distribution of dust and ionized gas is probably strongly affected by the presence of the embedded stars; one of the sources is a blister H II region, another has a bipolar structure, and the third exhibits asymmetric temperature structure. Spherically symmetric models are clearly not applicable to any of the clouds around these objects. The presence of protostellar objects throughout the region suggests that star formation has occurred nearly simultaneously in the whole molecular cloud rather than having been triggered sequentially from within. (31 refs.)

78975 Why high-latitude clouds in our Galaxy and the highly redshifted clouds observed in front of OSOs do not belong to the same parent population. A.M.Wolfe (Univ. of Pittsburgh, Pittsburgh, PA, USA).

Astrophys. J. Lett. Ed. (USA), vol.268, no.1, pt.2, p.L1-5 (1 May 1983). International Ultraviolet Explorer observations of high-latitude gas in our Galaxy reveal the presence of both C II and C IV absorption in the spectra of stars with $z > 2$ kpc. On the other hand, C II is generally absent from unbiased samples of QSO redshift systems with C IV absorption. Comparison between the equivalent-width distributions of the QSO sample and of the galactic sample (which is suitably corrected for contamination by disk absorption) shows that the probability that the two samples are drawn from the same parent population is less than 1% for C II and less than 10% for C IV. Thus it is highly unlikely that gaseous halos comprised of material with properties of the high-latitude gas are responsible for the bulk of known QSO redshift systems. (18 refs.)

78976 Ring ejection in Type II supernovae: 1E 0102.2-7219 in the Small Magellanic Cloud. I.R.Tuohy, M.A.Dopita (Mount Stromlo & Siding Spring Obs., Australian Nat. Univ., Woden, Australia).

Astrophys. J. Lett. Ed. (USA), vol.268, no.1, pt.2, p.L11-15 (1 May 1983). Presents a velocity map of the young oxygen-rich supernova remnant (1E 0102.2-7219) in the Small Magellanic Cloud, obtained with the Anglo-Australian Telescope. The velocity structure is complex and implies a high degree of asymmetry during the Type II supernova explosion. The velocity data can be modeled in terms of a severely distorted ring of ejecta. This result, together with the evidence for expanding rings in similar remnants, suggests nonspherical ejection to be an intrinsic characteristic of Type II supernovae. The authors have also obtained two-dimensional spectroscopy of the diffuse halo of emission which partially surrounds 1E 0102.2-7219. The halo emits in the He II $\lambda 4686$ line and is either a fossil H II region created by a UV flash accompanying the supernova, or alternatively, is being excited by intense UV radiation from the remnant itself. It is the first clear association of a high-excitation region with a supernova remnant. (26 refs.)

78977 Ultraviolet continuum and H₂ fluorescent emission in Herbig-Haro objects 43 and 47. R.D.Schwartz (Phys. Dept., Univ. of Missouri, St. Louis, MO, USA).

Astrophys. J. Lett. Ed. (USA), vol.268, no.1, pt.2, p.L37-40 (1 May 1983). The results of International Ultraviolet Explorer (IUE) short-wavelength spectra of the low-excitation Herbig-Haro objects HH 43 and HH 47 are reported. In HH 43 a number of emission lines in the Lyman band of H₂ from the excited state $1s_n^+ \nu=1, J=4$ are observed. The lines are produced by fluorescence from the H Ly α line which pumps the lower state $1s_n^+, \nu=2, J'=5$ which in turn is excited by a low-velocity shock wave. No evidence of emission from highly ionized gas is present in the UV spectra. Both objects exhibit a UV continuum which peaks in the vicinity of 1500 Å and which is probably caused by hydrogen two-photon emission enhanced by collisional excitation in a low-velocity shock. (23 refs.)

78978 Observation of ice mantles toward HD 29647. J.H.Goebel (NASA Ames Res. Center, Moffett Field, CA, USA).

Astrophys. J. Lett. Ed. (USA), vol.268, no.1, pt.2, p.L41-5 (1 May 1983). The water ice absorption band at 3.1 μ m has been observed in HD 29647, which is a late B-type star with an anomalous ultraviolet extinction curve. The interpretation is that ice mantles are present on the dust grains in the intervening cloud and that these mantles are responsible for suppressing the 2200 Å interstellar absorption feature. This is the first observation of both the 2200 Å region and the 3.1 μ m interstellar absorption feature toward the same star. A comparison of recent UV laboratory data of water ice with the UV spectrum of HD 29647 further supports the presence of water ice mantles in the same column density as that observed in the infrared. The diffuse interstellar features have been reported to be weakened in this star, consistent with their origin being on grain core surfaces, rather than in mantles or gaseous molecules. (30 refs.)

78979 On the possibly low H₂ formation rate in dense clouds. T.P.Snow (Dept. of Astrophysics, Univ. of Colorado, Boulder, CO, USA).

Astrophys. J. Lett. Ed. (USA), vol.269, no.2, pt.2, p.L57-9 (15 June 1983). It has been found for the ρ Ophiuchi cloud, and suggested for diffuse cloud cores in general, that H₂ has a lower formation rate than normally expected in diffuse clouds. It is proposed that this may be due to a reduction in grain surface area per unit volume, if the grains in these regions are enlarged due to coagulation. For the ρ Oph cloud, there is independent evidence that grain coagulation has occurred, so this hypothesis regarding H₂ formation has a more substantial basis than for other clouds, where the evidence for suppressed H₂ formation is less certain, and for which there is little information on grain sizes. (16 refs.)

78980 Spectrophotometric observations of a peculiar nitrogen-rich planetary nebula NGC 2440. R.Louise (Obs. de Marseille, Marseille, France).

J. Astrophys. & Astron. (India), vol.3, no.2, p.145-50 (June 1982). [received: June 1983] By using the Boller and Chivens spectrograph with a moderate dispersion (59 Å mm⁻¹) in the red spectral region, the author obtained 65 spectra covering the whole surface of the planetary nebula NGC 2440. Intensities of H α , [N II] λ 6548-6584 and [S II] λ 6717-6731 lines are derived. The nebula is known to be a nitrogen-rich nebula (Peimbert 1978) surrounded by secondary structures (Minkowski 1964). The unusual high value of the [N II]/H α in the central core (~ 3.0) is certainly due to the nitrogen overabundance occurring in that part of the nebula. Its variations from the centre to the outer regions are interpreted as a consequence of small-scale ionization structure (Capiotti, Cromwell and Williams 1971). (22 refs.)

78981 Observations of the supernova remnants HB 9 and IC 443 at 34.5 MHz. K.S.Dwarakanath, R.K.Shevgaonkar, C.V.Sastry (Raman Res. Inst., Bangalore, India).

J. Astrophys. & Astron. (India), vol.3, no.2, p.207-16 (June 1982). [received: June 1983] Observes the extended supernova remnants HB 9 (G160.5+2.8) and IC 443 (G189.1+2.9) at 34.5 MHz. A map of HB 9 is presented. The integrated flux density of HB 9 at 34.5 MHz is 750 \pm 150 Jy. The spectral index in the frequency range from 34.5 MHz to 2700 MHz is found to be constant (-0.58 ± 0.06) without any spectral break such as was reported earlier by Willis (1973). There is no significant variation of the spectral index across the remnant. The integrated flux density of IC 443 at 34.5 MHz is 440 \pm 88 Jy. The spectral index in the frequency range from 20 MHz to 10700 MHz is -0.36 ± 0.04 . The reduction in flux at very low frequencies (10 MHz) is attributable to free-free absorption in the interstellar medium and/or in the H II region S 249. (33 refs.)

78982 Interstellar ice grains in the Taurus molecular clouds. D.C.B.Whittet (Div. of Phys. & Astron., Preston Polytech., Preston, England), M.F.Bode, A.J.Longmore, D.W.T.Baines, A.Evans.

Nature (GB), vol.303, no.5914, p.218-21 (19 May 1983). Reports observations made in November 1981 using the United Kingdom Infrared Telescope (UKIRT) at Mauna Kea of the 3 μ m ice absorption feature in the spectra of several obscured stars in the Taurus interstellar clouds. The feature correlated in strength with extinction at visual wavelengths (A_V), and is present in stars with A_V as low as 4-6 mag, a remarkable result when compared with other regions of The Galaxy. Ice may be widespread in the Taurus clouds, vindicating previous ideas on grain composition and growth. (31 refs.)

78983 Optical emission from the SNRs G126.2+1.6, G206.9+2.3 and CTB 13. M.Rosado (Inst. de Astron., Univ. Nacional Autonoma de Mexico, Mexico City, Mexico).

Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.3, p.127-9 (July 1982). [received: April 1983]

Obtains narrow-band interference filter photographs in the light of H α , [S II] and [O III] of the SNRs G126.2+1.6 and G206.2.3 whose optical emission has been recently discovered, as well as that of the SNR CTB 13 which has been identified with some filaments on the PSS results. The first two SNRs

show high [S II]/H α and [O III]/H α line-ratios. The photograph of CTB 13 obtained in [O III] shows a spur coincident with the filaments visible on the PSS. A discussion of these individual SNRs is given. (15 refs.)

78984 Internal motions in H II regions. X. Are there optical H II regions associated with the Origen Loop? P.Pismis, I.Hasse (Inst. de Astron., Univ. Nacional Autonoma de Mexico, Mexico City, Mexico).

Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.3, p.161-5 (July 1982). [received: April 1983]

For pt.IX see *ibid.*, vol.5, no.2, p.79-85 (1981). The proposition that the emission nebulae Sharpless 254, 255, 257, 261 and 269 are physically related to the old SNR—the Origen Loop—is examined. Optical radial velocities obtained by the Fabry Perot method are given over the regions S261 and S269 while those of S254, 255 and 257 are published earlier. The kinematic distances of the H II regions as well as the photometric distances of their ionizing stars are discussed. On the basis of these distances it is concluded that of these five H II regions only S261 may belong to the Origen Loop. (20 refs.)

78985 Internal motions in H II regions. XI. The emission nebula Sharpless 206. P.Pismis, I.Hasse (Inst. de Astron., Univ. Nacional Autonoma de Mexico, Mexico City, Mexico).

Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.3, p.209-12 (July 1982). [received: April 1983]

For pt.X see *ibid.*, vol.5, no.3, p.161-5 (1982). Radial velocities at 142 points are obtained on the H II region S 206 by photographic Fabry-Perot interferometry using the reflectors with apertures of 2.1 meters at San Pedro Martir and 1-m at Tonantzintla. The overall velocity agrees with previous determinations. The velocities cover the western faint extensions of the nebula not studied hitherto. The velocity field is consistent with a directional expansion of S 206. (14 refs.)

78986 The filamentary nebula S 188. M.Rosado (Inst de Astron., Univ. Nacional Autonoma de Mexico, Mexico City, Mexico), K.B.Kwitter.

Rev. Mex. Astron. & Astrofis. (Mexico), vol.5, no.3, p.217-22 (July 1982). [received: April 1983]

The crescent shaped nebula Sharpless 188 is identified as a planetary nebula (PN) of Peimbert's (1981) Type I on the basis of its observed nebular spectrum. New FP interferometric work allows one to determine the motion of this nebula. The derived kinematical distance exceeds Cudworth's (1974) distance estimate supporting the idea that Peimbert's Type I PNs have larger ejected masses than typical PNs. A discussion about the origin of its non-spherical shape is also given. (19 refs.)

98.50 THE GALAXY, EXTRAGALACTIC OBJECTS AND SYSTEMS

78987 Spatially extended narrow emission-line gas in the Seyfert galaxy NGC 4151. T.M.Heckman (Astron. Program, Univ. of Maryland, College Park, MD, USA), B.Balick.

Astrophys. J. (USA), vol.268, no.1, pt.1, p.102-4 (1 May 1983). Presents narrow-band images of the emission-line gas in the type I Seyfert galaxy NGC 4151. These data are compared with optical spectroscopic data, radio continuum maps, and (especially) with new X-ray imaging data (Elvis, Briel, and Henry, 1982). Both the emission-line gas and X-ray gas are asymmetrically extended to the SW of the nucleus. The quiescent kinematics of the emission-line clouds would seem to preclude models in which the clouds themselves are accelerated out of the nucleus, subsequently collide with the ambient medium, and so produce X-rays. The authors argue that the extended emission-line region is ambient interstellar material which is photoionized by X-rays emitted from an adjacent region of shocked interstellar gas. The narrow, elongated morphology of the extended emission-line region would then suggest that the nucleus supplies energy to its environs in a collimated fashion. (17 refs.)

78988 Extended soft X-ray emission from NGC 4151. M.Elvis (Harvard-Smithsonian Center for Astrophysics, Cambridge, MA, USA), U.G.Briel, J.P.Henry.

Astrophys. J. (USA), vol.268, no.1, pt.1, p.105-10 (1 May 1983).

An Einstein HRI exposure of ~ 8000 s shows evidence for an extended emission region centered $\sim 5''$ to the SW of the nucleus of NGC 4151. This emission accounts for $\sim 15\%$ of the total HRI flux and is equivalent to a luminosity of $\sim 5 \times 10^{40}$ ergs s⁻¹. The X-rays do not appear to come from the radio jet and are more likely to be associated with the large forbidden emission line region. The authors consider three possible sources: a hot thermal plasma in pressure equilibrium with the optical line emitting clouds and confining them; shock heating of outflowing forbidden line clouds as they impact on the normal interstellar medium of the galaxy; enhanced star formation, stimulated by shocks originating from outflowing emission line clouds leading to an unusual concentration of SNR and massive X-ray binaries. (32 refs.)

78989 The galactic gamma-ray source population. C.P.Godfrey (Iowa State Univ., Ames, IA, USA).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.111-16 (1 May 1983).
The galactic gamma-ray source population as a whole is studied under the assumption that the discrete source are distributed in the same manner as the total galactic gamma-ray emissivity. The total emissivity distribution of high energy gamma rays (70 MeV < E < 5 GeV) as seen by the COS B satellite is derived via the geometrical unfolding technique. The assumption of proportionality between the discrete source component and the total emissivity at each point of the galactic disk then allows the relative distribution of the COS B-like sources to be found. This, together with the properties of the COS B catalog of sources, i.e. the total number of sources observed and the limiting flux sensitivity for source detection as a function of galactic longitude, can be used to derive parameters which describe the source population. (49 refs.)

78990 X-ray observations of 20 3CR radio galaxies and their environs. E.D.Feigelson, C.J.Berg (Dept. of Phys., MIT, Cambridge, MA, USA).

Astrophys. J. (USA), vol.269, no.2, pt.1, p.400-15 (15 June 1983).
Reports X-ray observations of a sample of 3CR radio galaxies using the Imaging Proportional Counter on the Einstein satellite. Possible relationships between X-ray emission and a variety of optical and radio properties are sought, partly to help determine whether the X-rays are produced predominantly in the active nucleus or in a gaseous intracuster medium. X-ray luminosity is statistically correlated with the radio power of the core, with the lobe radio power and with the steepness of the lobe radio spectrum at high frequencies. The complex interrelations between X-ray luminosities and radio core, radio lobe, optical nuclei, and galaxy clustering are discussed in detail. The data also provide constraints on synchrotron and inverse Compton production of X-rays in radio lobes and on mechanisms of lobe confinement. The authors discuss how correlations between X-ray and radio luminosities can be derived from flux-limited samples. (85 refs.)

78991 Mrk 744 and Mrk 1066: two Seyfert galaxies with strong absorption-line spectra. R.W.Goodrich, D.E.Osterbrock (Univ. of California, Santa Cruz, CA, USA).

Astrophys. J. (USA), vol.269, no.2, pt.1, p.416-22 (15 June 1983).
Spectrophotometric observations of the nuclei of two Seyfert galaxies, Mrk 744 and Mrk 1066, are reported. Both these objects have strong absorption-line spectra due to the underlying galaxies. A least squares fitting procedure is used to decompose the spectra into the galaxy contribution, the power-law featureless continuum, and the emission-line spectrum. Equivalent widths of the G, b, and E₂ absorption features are measured and the corresponding values of the fraction of power-law contribution at 4800 Å calculated and compared to the least squares results. It is suggested that Seyfert 1.8 galaxies like Mrk 744, and Seyfert 1.9 galaxies as well, may be objects in which the broad-line emitting region is seen nearly edge-on, so that the effects of extinction by dust are unusually large. (16 refs.)

78992 2-165 keV observations of active galaxies and the diffuse background. R.E.Rothschild (Univ. of California, San Diego, CA, USA), R.F.Mushotzky, W.A.Baity, D.E.Gruber, J.L.Matteson, L.E.Peterson.

Astrophys. J. (USA), vol.269, no.2, pt.1, p.423-37 (15 June 1983).
The HEAO 1 spectral observations of 12 active galaxies are presented in the 12-165 keV and 2-50 keV ranges. The mean spectrum of these galaxies is assumed to be representative of active galaxies in general. Then comparison of the mean active galaxy spectrum to the diffuse X-ray spectrum constrains the contribution of active galaxies to the diffuse flux, and gives upper limits to break energies in active galaxies. The data constrain the degree of number density evolution of active galaxies and point out the occurrence of nearly identical spectral indices, and dispersion in spectral index, from cores of active galaxies (as deduced from our measurements), 3CR radio sources, flat-spectrum radio sources, jets from active galaxies, and disks of spiral galaxies. This may indicate that the X-ray emission from the cores of active galaxies is also due to relativistic particles, as is believed to be the case for the radio sources. (60 refs.)

78993 Morphology of optical forms of N galaxies. W.W.Morgan, R.D.Dreier (Yerkes Obs., Williams Bay, WI, USA).

Astrophys. J. (USA), vol.269, no.2, pt.1, p.438-9 (15 June 1983).
Follows Weedman's (1977) suggestion of a spectroscopic definition for Seyfert galaxies, to present a simple four-box classification of the forms of N galaxies. The complete types for these galaxies must include a spectroscopic parameter that would show which of the Ns are also Seyferts—and the type of the Seyfert spectra in each case. (11 refs.)

78994 The transitory nature of the filaments in NGC 5128 (Centaurus A). J.A.Graham (Cerro Tololo Inter-American Obs., La Serena, Chile).

Astrophys. J. (USA), vol.269, no.2, pt.1, p.440-3 (15 June 1983).
New optical observations demonstrate differential velocities of at least 800 km s⁻¹ within a group of gaseous filaments near the middle NE radio lobe of the galaxy NGC 5128. These optical fragments are at a projected distance of 30 kpc from the main body of the galaxy and are associated with an extended source of soft X-rays. Compared with reasonable values for the average space velocity of the gas, the internal velocity spread is too high for it to have traveled in its present turbulent state over the full distance from the nucleus. The gaseous filaments, as observed, are evidently only temporary and will disperse over a time of the order of 10⁶-10⁷ years. (5 refs.)

78995 A multifrequency study of star formation in the blue compact dwarf galaxy I Zw 36. F.Viallefond (Obs. de Paris-Meudon, Paris, France), T.X.Thuan.

Astrophys. J. (USA), vol.269, no.2, pt.1, p.444-65 (15 June 1983).
Presents radio, near-infrared, optical, and ultraviolet observations of the blue compact dwarf galaxy I Zw 36 ≡ Mrk 209 ≡ Haro 29. The visible star formation region is associated with the core but is slightly shifted with respect to the H I peak column density. I Zw 36 has about a tenth of the solar metallicity. Its dust-to-oxygen abundance ratio by mass is discussed. The near-infrared observations indicate the presence of an old stellar population of G and K giants. Star formation models with an initial mass function of slope 1.5 (the Salpeter value is 1.35) and a burst age or duration of a few million years fit well the optical spectrophotometric measurements. To account for the metallicity, one previous burst of very short duration with a strength comparable to the present one is needed. Alternatively, no previous massive star formation is needed if there has been continuous star formation at a constant rate for the last 7 million years. The old stellar population can account for the virial mass only if it is spatially much more extended than the young population. In that case, low-mass stars must have formed in the past independently from the burst producing the massive stars. (46 refs.)

78996 Spectroscopic evidence for activity in the nuclei of normal spiral galaxies. W.C.Keel (Lick Obs., Univ. of California, Santa Cruz, CA, USA).

Astrophys. J. (USA), vol.269, no.2, pt.1, p.466-86 (15 June 1983).
The emission spectra of 29 spiral galaxies with low-ionization emission are studied in detail, using synthetic galaxy spectra to correct the observed spectra for the contribution of starlight. The resulting emission-line intensities and

ratios are compared to published models of shock-heated and power-law photoionized plasmas. The observed spectra are best described by models in which a weak flat-spectrum (power-law) radiation field photoionizes the gas; this nonthermal continuum is generally too weak to be seen directly in the optical. Broad H α emission extending over a total velocity range as great as 400 km s⁻¹, is identified in several 'normal' nuclei with strong low-ionization emission. The inferred nonthermal continuum and observed broad permitted lines indicate the presence of low-luminosity active nuclei in most, if not all, spiral galaxies. (80 refs.)

78997 The stability of a magnetically confined radio jet. H.Cohn (Dept. of Phys., Univ. of Illinois, Urbana, IL, USA).

Astrophys. J. (USA), vol.269, no.2, pt.1, p.500-12 (15 June 1983).
The linear stability against pinching modes of a model for a magnetically confined extragalactic radio jet is investigated. An analytic dispersion relation for these modes is obtained and then solved numerically. For comparison the dispersion relation for the Kelvin-Helmholtz pinching modes of a pressure confined jet is also solved numerically. The behavior of the modes is found to be fairly independent of the confinement mechanism. Subsonic and Mach 1 jets are found to be unstable to a single pinching mode at every wavenumber. In addition to this fundamental mode, supersonic jets have an infinite set of higher order ('reflection') pinching modes that enter at points of marginal stability. When the jet velocity is less than hypersonic, these reflection modes have large spatial growth rates and thus may be responsible for the observed knot structure of radio jets. (37 refs.)

78998 Can secondary infall produce flat rotation curves? C.Pryor, M.Lecar (Harvard-Smithsonian Center for Astrophysics, Cambridge, MA, USA).

Astrophys. J. (USA), vol.269, no.2, pt.1, p.513-30 (15 June 1983).
Performs a series of numerical experiments to simulate the formation of galactic halos by dissipationless secondary infall. The purpose is to test Gunn's (1977) suggestion that density profiles as shallow as r^{-2} could be produced when a surrounding region with greater than critical density falls in on a $\sim 10^{11} M_{\odot}$ galaxy which had formed earlier. As predicted, the maximum expansion density profiles were as shallow as r^{-2} , but these shallow profiles were not preserved in the subsequent infall. One reason for this was that the initial conditions which yielded shallow profiles at maximum expansion also enhanced the collective relaxation during the collapse, which steepened the final profiles. Another reason was that the infall adiabatically compressed the material in the outer halo less than that in the inner regions. This effect steepened the profile of the outer half of the mass and, like the collective relaxation, was more pronounced for shallow maximum expansion profiles. Both effects combined to prevent the formation of profiles shallow enough to explain the observed flat rotation curves of galaxies. (25 refs.)

78999 The variation of dust temperatures in Maffei 2. L.J.Rickard (Dept. of Phys. & Astron., Howard Univ., Washington, DC, USA), P.M.Harvey.

Astrophys. J. Lett. Ed. (USA), vol.268, no.1, pt.2, p.L7-9 (1 May 1983).
Reports far-infrared photometry for the central regions of Maffei 2. The fitted dust temperatures show a definite decline away from the nucleus. This supports the hypothesis that the molecular clouds close to the nucleus represent a different population from the disk clouds. Extragalactic studies that assume constant temperatures to convert CO integrated intensity to molecular hydrogen surface mass density may be in serious error. (20 refs.)

79000 Rapid X-ray variability from the Seyfert 1 galaxy NGC 4051. F.E.Marshall, S.S.Holt, R.F.Mushotzky (Lab. for High Energy Astrophysics, NASA Goddard Space Flight Center, Greenbelt, MD, USA), R.H.Becker.

Astrophys. J. Lett. Ed. (USA), vol.269, no.2, pt.2, p.L31-5 (15 June 1983).
Strong variable X-ray emission from the nearby low-luminosity Seyfert 1 galaxy NGC 4051 has been discovered during observations with the imaging proportional counter (IPC) of the Einstein Observatory. During one 2304 s observation, the X-ray flux more than doubled in an approximately linear fashion, and a 70% increase for 150 s was seen during another 968 s observation. The authors present evidence that the X-ray spectrum of NGC 4051 is unusually soft compared with Seyfert 1 galaxies or QSOs. The emission mechanism is probably not synchrotron or synchrotron self-Compton, but the emission can be plausibly explained by various black hole accretion models. (25 refs.)

79001 Low-ionization active galactic nuclei: X-ray or shock heated? J.P.Halpern (Harvard-Smithsonian Center for Astrophysics, Cambridge, MA, USA), J.E.Steiner.

Astrophys. J. Lett. Ed. (USA), vol.269, no.2, pt.2, p.L37-41 (15 June 1983).
Evaluates narrow-line ratios for a wide variety of active galactic nuclei, including those claimed to be shock heated. In the context of a Seyfert photoionization model, the entire range of observed narrow-line excitation conditions can be accounted for by varying a single parameter related to the photon flux. The characteristic [O II]:[O I]:[O III] line ratios which define Heckman's (1980) 'Liners' are reproduced, obviating the need to invoke shock heating for these low-ionization nuclei. X-ray data on a number of Liners provide preliminary evidence for an ionizing continuum. The Seyfert 1.8 and 1.9 galaxies (weak, broad wings) appear to be transition cases between Seyferts and Liners. The authors conclude that Liners are low-luminosity or obscured Seyfert nuclei, or both. The photoionization model also explains the large [N II]/H α ratio often seen in the nuclei of galaxies. (37 refs.)

79002 Radio continuum observations of the bar of NGC 1097. M.P.Ondrechen, J.M.Van Der Hulst (Dept. of Astron., Univ. of Minnesota, Minneapolis, MN, USA).

Astrophys. J. Lett. Ed. (USA), vol.269, no.2, pt.2, p.L47-50 (15 June 1983).
Radio continuum observations of NGC 1097 at 1465 MHz with the VLA reveal emission coincident with the straight, narrow dust lanes in the bar. The authors believe this is nonthermal emission produced by the shock compression of the gas, dust, and magnetic field in the bar. This shock compression is a common feature of models dealing with the gas flow in barred spiral galaxies. The results thus provide strong evidence that the predicted shock fronts to indeed exist. (36 refs.)

79003 Density gradients for disc- and halo-stars in the direction of the globular cluster NGC 7006. W.Becker, S.Karaali (Astron. Inst., Univ. of Basle, Binningen, Switzerland).

Astron. & Astrophys. Suppl. Ser. (France), vol.52, no.2, p.269-77 (May 1983).

A photographic RGU-photometry of 1810 stars down to the limiting magnitude $G=19^m$ has been carried out in a field of 0.29 square degrees near the globular cluster NGC 7006 ($\alpha=64^{\circ}$, $\delta=-19^{\circ}$). The possibilities of identifying main-sequence stars and late-type giants of both populations by means of the two-colour diagrams are discussed. No interstellar absorption could be detected in this direction. Density functions have been determined for main-sequence stars and late-type giants of Population I and for main-sequence stars of Population II. The Population I functions are compared with the ones valid for the solar neighbourhood reduced to the galactic latitude of the field ($D/\sin b$). The luminosity function for main-sequence stars of Population I within 400 to 800 pc has been determined and compared to the ones valid for

the solar neighbourhood and for $z=200$ pc. Finally the colour-magnitude diagrams of both populations are discussed. (9 refs.)

79004 Double galaxy investigations. I. Observations. W.G.Tift (Steward Obs., Univ. of Arizona, Tucson, AZ, USA). *Astrophys. J. Suppl. Ser. (USA)*, vol.50, no.3, p.319-89 (Nov. 1982). [received: May 1983]

Redshift information from 240 Å mm⁻¹ spectrograms is presented for 370 double galaxy systems from Karachensev (1972) including all pairs in that catalog with separation less than 80". An extensive error discussion utilizing internal and external (21 cm) comparisons provides calibration of systematic error and determines the uncertainty for a typical high weight optical redshift to be ± 65 km s⁻¹. Internal differential redshifts within single spectra using common lines achieve accuracies of 18-30 km s⁻¹, depending upon separation, and are available for ~200 pairs. Extensive information on emission and other properties is also provided. (20 refs.)

79005 Global stability of disk-bulge systems: spiral structure of disk galaxies. A.Ambastha, R.K.Varma (Phys. Res. Lab., Ahmedabad, India). *J. Astrophys. & Astron. (India)*, vol.3, no.2, p.125-44 (June 1982). [received: June 1983]

The spiral arms of disk galaxies are very sensitive to various morphological properties. The stability of self-gravitating annular disks surrounding the central rigid bulge component is studied in order to explain the transition from the tight spiral arms in Sa galaxies to rather open patterns in Sc galaxies as the central amorphous component diminishes. When the disk-to-bulge mass ratio is small, a tight pattern results restricted to the inner regions of the disk. This pattern opens up and occupies larger disk areas as the disk component becomes comparable to the bulge. It is found that unstable modes of the annular disk can be suppressed by increasing the thermal pressure sufficiently. (28 refs.)

79006 Compact radio cores and the relation between the radio and optical axes of elliptical galaxies. V.K.Kapahi, D.J.Saikia (Radio Astron. Centre, Tata Inst. of Fundamental Res., Bangalore, India). *J. Astrophys. & Astron. (India)*, vol.3, no.2, p.161-71 (June 1982). [received: June 1983]

Investigates the reported tendency for the extended radio structures associated with bright elliptical galaxies to be oriented preferentially along the optical minor axes. It is found that such a tendency exists only for those galaxies in which the compact radio cores coincident with their nuclei are quite prominent. If the galaxies are divided into two groups according to whether their cores account for less than or greater than 10 per cent of the total flux density at 2.7 GHz, the angle ϕ (between the radio axis and the optical minor axis) appears to be uniformly distributed between 0° and 90° for the former, but is nearly always <30° for the latter group. One possible explanation is that the radio emission from compact cores suffers thermal absorption by ionized gas that is distributed differently in the two groups. (38 refs.)

79007 The differential rotation of The Galaxy and the change of pulsar period. Rong Jianxiang, Xia Yifei (Dept. of Astron., Nanjing Univ., China). *Kexue Tongbao (Foreign Lang. Ed.) (China)*, vol.28, no.3, p.352-6 (March 1983).

The rate of periodical change, \dot{P} , is one of the most important parameters for pulsars, for it provides a lot of valuable information for studying the physical processes of them. At present, the intrinsic mechanisms of pulsar radiation responsible for the change of radio pulse period are being discussed heatedly on a world scale, but research into the external causes that are independent of the intrinsic mechanisms that affect the change has been neglected. Among the external causes, the effect of differential rotation of the Galaxy on the change of pulsar period is a subject the authors have studied. Owing to the presence of differential rotation of the Galaxy, for each pulsar there exists a factor affecting the rate of periodical change of the pulsar. Therefore this effect is of universal significance. (7 refs.)

79008 Inversion symmetry of radio lobes in extragalactic sources. Gopal-Krishna, S.M.Chitre (Radio Astron. Centre, Tata Inst. of Fundamental Res., Bangalore, India). *Nature (GB)*, vol.303, no.5914, p.217-18 (19 May 1983).

The collimated beams of relativistic particles ejected from the central engines of extragalactic radio sources are traced out by means of the jet-like features of nonthermal radio emission which are observed to extend up to a few hundred kiloparsecs. These jets exhibit departures from linearity in a variety of ways. In some less luminous large radio galaxies, the jets show structures with a distinctive S-shaped bending (inversion symmetry) at distances of the order of 100 kpc from the galactic nucleus. The authors propose that such a sharp bending can result from the interaction of the relativistic beam fluid with faint, rotating shells similar to those seen around some nearby galaxies. The possible implications of this hypothesis are discussed. (40 refs.)

79009 Direct evidence for a massive galactic halo. M.R.S.Hawkins (Royal Obs., Edinburgh, Scotland). *Nature (GB)*, vol.303, no.5916, p.406-8 (2 June 1983).

Reports the discovery of a very distant galactic RR Lyrae star, R15. Spectroscopic observations of the object show that it has a high negative radial velocity, implying a lower limit to the mass of the Galaxy of $1.4 \times 10^{12} M_{\odot}$. (10 refs.)

79010 Measurement of the 0.511 MeV γ -ray line from the galactic center. J.O.D.Jardim, J.L.Benson, M.V.A.Jardim, I.M.Martin (Inst. de Pesquisas Espaciais, Rio de Janeiro, Brazil). *Rev. Mex. Astron. & Astrofis. (Mexico)*, vol.5, no.3, p.131-3 (July 1982). [received: April 1983]

The detection of the 0.511 MeV electron-positron annihilation line coming from the galactic center can provide the means to estimate the rate of positron production and to test some theoretical sources of positrons. The authors present the result of the measurements of the 0.511 MeV line flux made in a gamma-ray experiment on board a stratospheric balloon. (12 refs.)

79011 The evolution of clusters of galaxies. I. Very rich clusters. D.O.Richstone, E.M.Malumuth (Dept. of Astron., Univ. of Michigan, Ann Arbor, MI, USA). *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.30-46 (1 May 1983).

A multiple one-body Monte Carlo code is developed which follows the evolution of galaxies in a steady cluster potential under the influence of dynamical friction, two-body relaxation, tidal stripping, and galaxy mergers. The authors show that the formation of a very massive cluster galaxy depends critically on the number of galaxies, the initial division of cluster material between galaxies and a smooth intracluster medium (ICM), the mass spectrum of the galaxies, and luck. Using a Schechter mass spectrum with no initial intra-cluster medium, the authors find that 30% of the simulations produce a very massive galaxy at the cluster center. This fraction can be altered by changing the mass spectrum or the ICM fraction. The mass, location, and low velocity relative to the cluster center of this very massive object, when it is produced, are consistent with identifying it as a cD galaxy. By the end of all simulations, less than half of the mass in the central region of the cluster is bound to galaxies. (50 refs.)

79012 The Cancer Cluster: an unbound collection of groups. G.D.Bothun, M.J.Geller, T.C.Beers, J.P.Huchra (Harvard-Smithsonian Center for Astrophys., Cambridge, MA, USA). *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.47-55 (1 May 1983).

Presents a surface density contour map of the Cancer Cluster derived from galaxy counts in the Zwicky catalog. The contour map shows that the galaxy distribution is clumpy. When this spatial distribution is combined with nearly complete velocity information, the clumps stand out more clearly; there are significant differences in the mean velocities of the clumps which exceed their internal velocity dispersions. The Cancer Cluster is not a proper 'cluster' but is a collection of discrete groups, each with a velocity dispersion $\sigma_v \approx 300$ km s⁻¹, separating from one another with the cosmological flow. The mass-to-light ratio for galaxies in the main concentration is discussed. (26 refs.)

79013 Redshift quantization in compact groups of galaxies. W.J.Cocke, W.G.Tift (Steward Obs., Univ. of Arizona, Tucson, AZ, USA). *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.56-9 (1 May 1983).

Radio data (21 cm) on the redshifts of galaxies in small groups are analyzed for the previously 72 km s⁻¹ quantization. The redshift differentials definitely clump about multiples of 72 km s⁻¹, at a confidence level of 99.5%. The detailed deviations of the data from exact quantization are discussed in terms of the superposition of redshift states. (13 refs.)

79014 A statistical VLBI study of milli-arcsecond cores in extragalactic radio sources. R.A.Preston, D.D.Morabito (Jet Propulsion Lab., California Inst. of Technol., Pasadena, CA, USA), D.L.Jauncey. *Astrophys. J. (USA)*, vol.269, no.2, pt.1, p.387-99 (15 June 1983).

VLBI observations at 2.3 GHz have been performed with a baseline of $\sim 8 \times 10^7$ wavelengths on a complete sample of 103 sources from the Parkes $\pm 4^\circ$ catalog. Compact milli-arcsecond cores were found in 35% of all sources: 80% of quasars, only 10% of galaxies, and 20% of empty field sources. Virtually all of the sources appear to be at least partially resolved. For quasars, the percentage of the source flux density found to be coming from milli-arcsecond cores increased with increasing radio spectral index, radio variability and optical redness. Quasars with extended radio structure ($\geq 10''$) seem more likely to possess a detectable milli-arcsecond core than do extended radio galaxies. The absence of a strong correlation between quasar milli-arcsecond structure and redshift is evidence for a lack of strong physical evolution in quasars, a hypothesis which is in agreement with previous studies of the size evolution of both quasar large-scale radio structure and radio lobe hot spots. (35 refs.)

79015 The variability of the optical counterparts of four extragalactic radio sources. H.R.Miller (Dept. of Phys. & Astron., Georgia State Univ., Atlanta, GA, USA). *Astron. & Astrophys. Suppl. Ser. (France)*, vol.52, no.2, p.289-91 (May 1983).

Theoretical variability of four extragalactic radio sources has been studied using the archival plates at the Harvard College Observatory. Three of these sources, PKS 1123+264, B2 1132+303, and 4C 18.36, were conclusively found to exhibit significant optical variability. No conclusive evidence was found for optical variability for B2 1128+315 with a range $\Delta m < 0.3$ magnitude, based on a limited number of plates. (16 refs.)

79016 Measurement of unambiguous rotation measures of extragalactic sources. L.Rudnick (Dept. of Astron., Univ. of Minnesota, Minneapolis, MN, USA), E.Zukowski, P.P.Kronberg. *Astron. & Astrophys. Suppl. Ser. (France)*, vol.52, no.2, p.317-21 (May 1983).

Reports the results of polarization measurements conducted specifically to check for the existence of very high Faraday rotation measures, which might otherwise have been undetected. Polarization measurements are presented for 24 extragalactic radio sources at 4 contiguous bands around λ 9 cm, from observations at the NRAO 300' telescope. These measurements can be used to derive rotation measures (and limits) which are free from π phase ambiguities around λ 9 cm. Data cannot be made consistent with arbitrarily large rotation measures. Revised rotation measures and initial position angles are presented for the observed sources. (5 refs.)

79017 VLA observations of hot spots in high luminosity radio sources. R.T.Schilizzi (Netherlands Foundation for Radio Astron., Dwingeloo, Netherlands), V.K.Kapahi, S.G.Neff. *J. Astrophys. & Astron. (India)*, vol.3, no.2, p.173-87 (June 1982). [received: June 1983]

VLA observations at 6 cm have been made of 16 distant luminous 3C sources that appeared to be unresolved or slightly resolved in Cambridge maps but which were known from VLBI observations to contain significant fine structure on the scale of about 1 kpc in their lobes. The general morphology of these sources is very similar to that of their nearby powerful counterparts; most of the lobes contain low brightness tails which are often directed from the hot spots towards the associated optical object. The hot spots are generally unresolved by the VLA observations; in 3C 254, 3C 268.4 and 3C 352, one of the lobes contains two hot spots. (20 refs.)

79018 The identification of CTA 21. D.A.Allen (Anglo-Australian Obs., Epping, NSW, Australia), A.E.Wright, J.G.Ables. *J. Astrophys. & Astron. (India)*, vol.3, no.2, p.189-92 (June 1982). [received: June 1983]

CTA 21 has long been the outstanding example of a strong, compact radio source lacking an optical identification. The authors report the discovery at infrared wavelengths of the counterpart of CTA 21, and show that its spectral shape is unusual. (9 refs.)

79019 Extragalactic 1 millimeter sources: simultaneous observations at centimeter, millimeter, and visual wavelengths. R.Landau, T.W.Jones (Astron. Dept., Univ. of Minnesota, Minneapolis, MN, USA), E.E.Epstein, G.Neugebauer, B.T.Soffer, M.W.Werner, J.J.Puschell, T.J.Balonek. *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.68-75 (1 May 1983).

Observations simultaneously made at visual (B, V, and R) wavelengths, at 1, 1.4, and 3.4 mm and at 1.3, 2, 6, and 20 cm of 9 QSOs and BL Lac objects are reported. The range of the millimeter-visual spectral index may indicate that the electrons radiating synchrotron emission in this portion of the spectrum are not subjected to large radiative losses, and therefore relative bulk motion with Doppler factors ~ 10 are required. The visual spectral index is much more broadly distributed. The spectral energy distributions have not changed much in the last 2-5 years except for 2251+15 and perhaps 0235+164. Only 1749+09 shows a sharp spectral break shortward of 1 mm. (39 refs.)

79020 The incidence of 21 centimeter absorption in QSO redshift systems selected for Mg II absorption: evidence for a two-phase nature of the absorbing gas. F.H.Briggs, A.M.Wolfe (Dept. of Phys. & Astron., Univ. of Pittsburgh, Pittsburgh, PA, USA).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.76-89 (1 May 1983).

A search for 21 cm absorption in the continua of 15 radio-bright QSOs reveals that 21 cm absorption occurs in two out of 18 redshifted clouds selected for Mg II absorption. There is no evidence that optical properties such as Mg II equivalent width, Mg II double ratio, or Mg I equivalent width are correlated with 21 cm optical depth. The lack of correlation between optical and radio absorption properties is related to the multi-component nature of the absorbing gas. While most of the narrow velocity components detected in this gas may not contain enough H I to produce 21 cm absorption, they still dominate saturated equivalent widths of UV resonance lines owing to the large internal velocity interval which they span. Occasionally, most of the H I is in one or more narrow components which produce detectable 21 cm absorption, but which make negligible contribution to optical equivalent widths. Lower limits are placed on the spin temperature of three Mg II systems, which rule out galactic disks as the absorption sites. A two-

phase model is suggested to unify the entire sample of Mg II systems. (57 refs.)

79021 Quasar evolution derived from the Palomar Bright Quasar Survey and other complete quasar surveys. M.Schmidt (Palomar Obs., California Inst. of Technol., Pasadena, CA, USA), R.F.Green.

Astrophys. J. (USA), vol.269, no.2, pt.1, p.352-74 (15 June 1983).

Presents the Bright Quasar Survey (BQS) consisting of 114 objects to an average limiting magnitude $B=16.16$ over an area of 10714 deg². There are 92 quasars with $M_B < -23$ in the sample. The authors use the BQS and complete samples from published surveys to derive models of the statistical evolution of quasars. The increase of space density with redshift depends strongly on absolute luminosity, being close to zero for low-luminosity quasars. Detailed predictions are given for the distribution of redshifts and magnitudes and for the total counts based on the evolution models. (65 refs.)

79022 Neutral hydrogen absorption in the quasar 3C 268.4: possible evidence for galactic halo clouds. A.D.Haschick (Haystack Obs., Westford, MA, USA), P.C.Crane, W.A.Baan.

Astrophys. J. Lett. Ed. (USA), vol.269, no.2, pt.2, p.L43-6 (15 June 1983).

Detects neutral hydrogen absorption at 21 cm wavelengths in the quasar-galaxy pair 3C 268.4/NGC 4138. The absorption spectrum exhibits two features which are separated by 65 and ~ 120 km s⁻¹, respectively, from the center velocity of 880 km s⁻¹ of the neutral hydrogen emission profile from NGC 4138. The line of sight to the quasar 3C 268.4 is separated by ~ 14 kpc (2.9') from NGC 4138 and lies very close ($< 5^\circ$) to the minor axis of the galaxy where the radial component of its rotation velocity is small. This leads to the suggestion that, in view of the large relative velocities of the neutral hydrogen clouds producing the observed absorption features, they are situated in the halo region rather than in the disk of the galaxy. The detection of this second example of absorption in a close quasar-galaxy pair further weakens the argument for association of the quasar with the galaxy. (22 refs.)

79023 X-ray studies of quasars with the Einstein Observatory. III. The 3CR sample. H.Tananbaum, J.F.C.Wardle, G.Zamorani, Y.Avni (Harvard-Smithsonian Center for Astrophysics, Cambridge, MA, USA).

Astrophys. J. (USA), vol.268, no.1, pt.1, p.60-7 (1 May 1983).

For pt.II see ibid., vol.245, no.2, p.357-74 (1981). Using the Einstein Observatory, the authors have detected X-ray emission from each of the 33 3CR quasars in Schmidt's complete sample. The authors observe a rather narrow distribution of X-ray luminosity compared to the distributions of radio and optical luminosity. The X-ray (2 keV) luminosity is strongly correlated with optical (2500 Å) luminosity, while there is no evidence within the sample for a dependence of X-ray luminosity on redshift or on total radio (5 GHz) luminosity. The authors derive an estimate of the X-ray luminosity distribution function for 3CR quasars and discuss the cosmological evolution of the X-ray luminosity function. For 3CR quasars which have a 'triple' radio structure the authors find a correlation between X-ray luminosity and radio luminosity of the central radio component. (34 refs.)

79024 The optical identification content of the Einstein Observatory deep X-ray survey of a region in Pavo. R.E.Griffiths, S.S.Murray, R.Giacconi, J.Bechtold (Harvard-Smithsonian Center for Astrophysics, Cambridge, MA, USA), P.Murdin, M.Smith, H.T.MacGillivray, M.Ward, J.Danziger, J.Lub, B.A.Peterson, A.E.Wright, M.J.Batty, D.L.Jauncey, D.F.Malin.

Astrophys. J. (USA), vol.269, no.2, pt.1, p.375-86 (15 June 1983).

Results are presented from the Einstein deep X-ray survey in Pavo, with correlated optical and radio observations of a complete sample of candidate identifications. There are 16 X-ray sources detected with positional accuracy better than 10", of which five are identified, with a further seven (and a maximum nine) probable identifications. Of the identified sources, four are QSOs with J -magnitude ~ 20 (one is an inverted spectrum radio source) and one is associated with extended emission from a pair or cluster of galaxies. Of the probable identifications, one is a galaxy and the rest are a subset of a yellow stellar object population which may also be QSOs. Identifications with QSOs and QSO candidates with $J < 24$ account for 60-80% of the detected sources. (34 refs.)

79025 X-ray nebular models. T.R.Kallman, R.McCray (Joint Inst. for Lab. Astrophys., Univ. of Colorado, Boulder, CO, USA).

Astrophys. J. Suppl. Ser. (USA), vol.50, no.3, p.263-318 (Nov. 1982).

[received: May 1983]

Theoretical models are presented for the temperature and ionization structure of spherically symmetric, constant density, gaseous nebulae surrounding compact X-ray sources and for the optical, UV, and X-ray spectra emerging from the nebulae. The structure is determined by assuming a local balance between heating and cooling in the gas, and the radiation field is found by solving a simplified equation of transfer. The calculations include an accurate and comprehensive treatment of the atomic processes affecting the state of the gas and the radiation field. The destruction of line radiation during resonance scattering causes models to be significantly hotter and more highly ionized than previous models of the same type. Model results are presented for a wide variety of gas densities and X-ray source spectra, scaling laws which allow these results to be generalized to a wide variety of astrophysical solutions are discussed, and column densities of multiply charged species are tabulated. (92 refs.)

- 79027** The irregular distribution of galaxies and the anisotropies in the microwave background photons. C.Ceccarelli, F.Melchiorri, L.Pietranera (Istituto di Fisica, Univ. di Roma, Roma, Italy), G.Dall'Oglio, B.O.Melchiorri. *Astrophys. J. Lett. Ed. (USA)*, vol.269, no.2, pt.2, p.L27-9 (15 June 1983). An infrared search for the Sunyaev-Zeldovich effect toward the intergalactic 'void' discovered by Kirshner et al. (1981) has given a null result within 1×10^{-4} K at 1 standard deviation. The result implies that the change of the Comptonization parameter toward the hole is less than 2×10^{-2} . From the hypothesis that the hot gas is absent in the hole, the authors obtain an upper limit 0.5 for the normalized density of the extragalactic gas. (12 refs.)
- 79028** Cosmic noise observations at high radio frequencies. M.Kotaki, I.Kuriki, C.Katoh, H.Sugiuchi. *Rev. Radio Res. Lab. (Japan)*, vol.28, no.146, p.387-97 (June 1982). In Japanese. Using the equipments on-board ISS-b, the average galactic radio noise has been obtained at the frequencies of 5, 10 and 25 MHz, and the noise powers from the galactic centre and anti-centre at 2.5, 5, 10 and 25 MHz. Generally, the antenna used for receiving on space vehicles has so wide an aperture in most cases, it becomes difficult to distinguish the direction of coming radio waves. Since ISS-b has the circular orbit of about 1100 km altitude, the strength of the galactic noise from the centre and anti-centre can be distinguished by the reason that the galactic centre is occulted by the Earth at a certain position on an orbit. The average temperatures of the galactic radio noise at the frequencies of 5, 10 and 25 MHz have the values of $(1.71 \pm 0.48) \times 10^6$ K, $(4.15 \pm 1.05) \times 10^6$ K, and $(3.47 \pm 1.07) \times 10^6$ K, respectively. The radiated power coming from the direction of the galactic centre is higher than that of the anticentre by 2.2-3.5 dB at high frequency range. (10 refs.)

- 79029** Can graininess in the early Universe make galaxies?. B.J.Carr (Inst. of Astron., Univ. of Cambridge, Cambridge, England). *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.1-16 (1 May 1983). Examines whether the density fluctuations required to explain galaxies and their clustering could have arisen spontaneously in an initially Friedmann Universe as a result of statistical effects associated with the Universe developing nonlinear lumps. Such graininess could be produced whenever the Universe underwent a phase transition, and the associated fluctuations would arise either from an intrinsic randomness in the grain formation process or from the grains developing small-scale motions. In both cases the fluctuations would have the same distinctive form at their inception, and the authors show how they would evolve thereafter. Even if the grain-induced fluctuations cannot produce galaxies directly, they may still be able to produce objects smaller than galaxies. Since astrophysical processes associated with these objects could themselves produce large-scale density fluctuations, it may be possible to generate galaxies and the observed correlation function from the grain effect indirectly. (78 refs.)
- 79030** Cosmological self-similar shock waves and galaxy formation. E.Bertschinger (Princeton Univ. Obs., Princeton, NJ, USA). *Astrophys. J. (USA)*, vol.268, no.1, pt.1, p.17-29 (1 May 1983). A new family of similarity solutions is found for a point blast in a $\Omega=1$ Friedmann cosmology (Einstein-de Sitter Universe). The given solutions are valid several Hubble times after an explosion. Initially the shock wave formed satisfies the Sedov solution for adiabatic evolution in a constant medium, but it is modified by the cosmological expansion to form a self-similar thin dense shell which cools by adiabatic expansion and is unstable to gravitational fragmentation and collapse. The shock solution is applied to the explosive amplification model of galaxy formation of Ostriker and Cowie (1981). (34 refs.)

- 79031** Counterpart of the Kasner model in Brans-Dicke theory. V.B.Johri (Dept. of Math., Indian Inst. of Technol., Madras, India), G.K.Goswami. *Aust. J. Phys. (Australia)*, vol.36, no.2, p.235-7 (1983). The authors present a simple and elegant generalization of the Kasner model in Brans-Dicke (BD) theory by solving the BD field equations corresponding to the Bianchi type I metric. (2 refs.)
- 79032** Particle physics and the new cosmology. P.J.Steinhardt (Univ. of Pennsylvania, Philadelphia, PA, USA). *AIP Conf. Proc. (USA)*, no.98, p.343-57 (1982). [received: May 1983] (Conference on Particles and Fields - 1982, College Park, MD, USA, 28-30 Oct. 1982). During the past year, astounding progress has been made in the development of a radically new theory of the evolution of the early Universe. The new theory derives from the possibility that the Universe underwent a symmetry breaking phase transition in its early history that was strongly first order. During such a transition, the Universe can supercool into a metastable phase with a large vacuum energy density which results in a period of exponential expansion. It has recently been shown that in special types of first order transitions the Universe can escape from the metastable phase to a stable phase. Without a vacuum energy density contribution to the total energy density, the Universe returns to the expansion rate found in the hot big bang model. The existence of an epoch of exponential growth leads to a natural explanation of the cosmological homogeneity, isotropy, flatness, monopole and domain wall problems that plague the standard hot big bang model. The new cosmology has also been shown to lead to a (nearly) scale invariant spectrum of density perturbations in the early Universe, just the spectrum many cosmologists believe is necessary to explain the evolution of galaxies and clusters in our Universe. - 79033** Larger numbers hypothesis. II. Electromagnetic radiation. P.J.Adams (Phys. Dept., Univ. of Puget Sound, Tacoma, WA, USA). *Int. J. Theor. Phys. (USA)*, vol.22, no.5, p.421-36 (May 1983). For pt.I see *ibid.*, vol.21, p.607 (1982). The author develops the theory of electromagnetic radiation in the units covariant formalism incorporating Dirac's large numbers hypothesis (LNH). A direct field-to-particle technique is used to obtain the photon propagation equation which explicitly involves the photon replication rate. This replication rate is fixed uniquely by requiring that the form of a free-photon distribution function be preserved, as required by the 2.7K cosmic radiation. One finds that with this particular photon replication rate the units covariant formalism developed in part I actually predicts that the ratio of photon number to proton number in the Universe varies as $t^{1/4}$ precisely in accord with LNH. The cosmological red-shift law is also derived and it is shown to differ considerably from the standard form of $\nu R = \text{const.}$ (11 refs.)
- 79034** Large numbers hypothesis. IV. The cosmological constant and quantum physics. P.J.Adams (Phys. Dept., Univ. of Puget Sound, Tacoma, WA, USA). *Int. J. Theor. Phys. (USA)*, vol.22, no.5, p.461-7 (May 1983). For pt.III see *ibid.*, vol.22, no.5, p.437 (1983). In standard physics quantum field theory is based on a flat vacuum space-time. This quantum field theory predicts a nonzero cosmological constant. Hence the gravitational field equations do not admit a flat vacuum space-time. This dilemma is resolved using the units covariant gravitational field equations. The author shows that the field equations admit a flat vacuum space-time with nonzero cosmological constant if and only if the canonical LNH is valid. This allows an interpretation of the LNH phenomena in terms of a time-dependent vacuum state. If this is correct then the cosmological constant must be positive. (16 refs.)
- 79035** The influence of neutrino rest mass on Dirac cosmology. Su Rukung (Dept. of Phys., Fudan Univ., Shanghai, China), Zhang Shiwei. *Kexue Tongbao (Foreign Lang. Ed.) (China)*, vol.28, no.3, p.325-7 (March 1983). Under the framework of unified Dirac cosmology, the influences of neutrino rest mass on Dirac cosmology are investigated. (4 refs.)
- 79036** A special law of variation for Hubble's parameter. M.S.Berman (Dept. de Fisica, Inst. Tecnológico de Aeronautica, Sao Paulo, Brazil). *Nuovo Cimento B (Italy)*, vol.74B, ser.2, no.2, p.182-6 (11 April 1983). A law of variation for Hubble's parameter in evolutionary models, that yields a constant value for the deceleration parameter, is presented. It leads naturally to the exclusion of open universes. (2 refs.)
- 79037** Generalised cosmological Friedmann equations and the de Sitter solution. A.V.Minkevich (Dept. of Phys., Byelorussian State Univ., Minsk, Byelorussian SSR). *Phys. Lett. A (Netherlands)*, vol.95A, no.8, p.422-4 (23 May 1983). It is shown that the generalised cosmological Friedmann equations in the gauge theory of gravitation obtained earlier have solutions with the de Sitter metric and vanishing as well as nonvanishing torsion. (20 refs.)
- 79038** Dynamical reduction of internal dimensions in the early Universe. T.Dereli (Dept. of Phys., Middle East Tech. Univ., Ankara, Turkey), R.W.Tucker. *Phys. Lett. B (Netherlands)*, vol.125B, no.2-3, p.133-5 (26 May 1983). An $(n+4)$ dimensional de Sitter model is constructed in which the metric scale factor for space-time expands exponentially in cosmic time while the internal space scale factor contracts exponentially. (7 refs.)
- 79039** Do we live inside a domain wall?. V.A.Rubakov, M.E.Shaposhnikov (Inst. for Nuclear Res., Acad. of Sci., Moscow, USSR). *Phys. Lett. B (Netherlands)*, vol.125B, no.2-3, p.136-8 (26 May 1983). The authors discuss the possibility that space-time has $(3+N)+1$ dimensions, but ordinary (light) particles are confined in a potential well which is narrow along N spatial directions and flat along three others. A five-dimensional model is considered in which this picture arises naturally. In a Universe of this type, processes looking like $e^+e^- \rightarrow$ nothing are possible at high energies. (7 refs.)
- 79040** Antiproton interactions with light elements as a test of GUT cosmology. V.M.Chechetkin, M.Yu.Khlopov (Inst. of Appl. Math. M.V. Keldysh, Moscow, USSR), M.G.Sapozhnikov. *Riv. Nuovo Cimento (Italy)*, vol.5, ser.3, no.10, p.1-79 (1982). The review starts with a brief description of the modern views on the evolution of the Universe. After that the authors discuss the problem of the existence of antimatter in the Universe and its possible astrophysical observational effects. They show that unique information on the possible presence of antimatter at the stage of radiation domination in the Universe ($t < 10^{13}$ s) may be obtained from the study of $p^0\text{He}$ annihilation. The difficulties of early attempts to include antimatter in cosmological considerations are described. The sources of antimatter, predicted by some GUTs, are discussed. They consider the physics of primordial black holes (their formation and evaporation), the formation and annihilation of antimatter domains, the relationship between these sources of antimatter and the phase transitions in the early Universe as well as heavy metastable particles predicted by GUTs. Some aspects of the theory of galaxy formation are in close touch with these prob-

lems. The observed abundances of light elements and their possible changes due to annihilation are discussed. In conclusion the necessary measurements and the restrictions on the parameters of GUT models which may be obtained from these measurements are considered. (94 refs.)

79041 Quantization of a homogeneous isotropic cosmological model in five-dimensional field theory. Yu.S.Vladimirov, V.V.Kislov (Moscow State Univ., Moscow, USSR).

Theor. & Math. Phys. (USA), vol.53, no.1, p.970-8 (Oct. 1982). Translation of: *Teor. & Mat. Fiz. (USSR)*, vol.53, no.1, p.43-54 (Oct. 1982).

A homogeneous isotropic cosmological model is quantized in the framework of five-dimensional field theory (unified theory of gravitation, electromagnetism, and a scalar field). A two-dimensional equation of DeWitt type with signature $(+ -)$ is obtained, which ensures the dynamics in the quantum variant of the theory. It is shown that the evolution of the quantum cosmological model is due to processes of redistribution of the matter in the Universe between its different forms. (12 refs.)

The economic use of electric road vehicles in a changing environment

PPL Conference Publication 15

This volume contains the papers presented at the 2nd International Electric Vehicle Development Group conference, held in Sheffield, England, 23rd & 24th May 1978, to examine the factors involved in the implementation of large numbers of high performance vehicles and to draw upon the experience of those now operating delivery and public passenger electric road vehicles.

The conference was organised by the Electric Vehicle Development Group, with the support of the National Freight Corporation, the National Bus Company, the International Union of Public Transport, the Electrical Research Association, the Lead Development Association, the Chartered Institute of Transport, the International Road Transport Union, the South Yorkshire Passenger Transport Executive, the Greater Manchester Passenger Transport Executive, the Greater London Council, and Electronics & Power.

The rising cost of fuels and projected shortages will encourage a diversification of transport into systems which are less energy intensive and not dependent on hydrocarbon fuels. Patterns of land use will alter and people will tend to move back into towns, where they

will require both higher economic standards and an improved quality of life. The electric vehicle is the only form of transport which can provide the level of transport required by an active urban centre and at the same time make towns attractive places to live in. The authors of papers presented at the conference represent international research organisations, government departments, manufacturers and transport operators.

October 1978, 13 papers, 110pp., 297 x 210mm, photolitho, soft covers, ISBN 0 906048 08 7, price £11.50 UK, \$23.95 in the USA and Canada, £13.50 Elsewhere

Inquiries and orders with remittances, should be sent to.

Gas discharges

IEE Conference Publication 165

The papers presented at the 5th international conference on gas discharges have now been published as number 165 in the IEE Conference Publication series. The conference held in Liverpool, England in September 1978 was sponsored by the IEE Science, Education and Management Division in association with the IEEE, the IoP, the IERE, and the Welding Institute.

Topics covered include gas blast switchgear, plasma radiation and diagnostics, corona discharges, long sparks, arcs, and high voltage technology. Fuses, radio-frequency

and glow discharges, pre-breakdown phenomena, vacuum switches and electrode phenomena, and high pressure sparks are also covered.

91 papers, 345 pp., 297 x 210 mm, photolitho, ISBN 0 85296 192 8, September 1978, soft covers, price £16.00 UK, £19.00 Overseas

Inquiries, and orders with remittances should be sent to:

COMPUTER & CONTROL ABSTRACTS

A Complete Information Service in Computer Science and Control Engineering

● Coverage

Over 30,000 references are included each year. These are selected by scanning about 2,800 journals and the proceedings of over 500 conferences. In addition coverage is given of books, reports and dissertations.

● What Information is Included?

Each reference in CCA includes the following information:

Title of paper

All author's names and affiliation of first author

Source of paper (eg name of journal, volume and issue number, page numbers and date of publication)

100-150 word abstract of the reference.

● Ease of use

Careful classifying and indexing of entries puts information at your fingertips. References are classified under 250 headings, allowing you to go straight to the information of most interest to you. (A summary of the classification appears in every issue).

These six separate indexes are included in each issue:

Subject guide

Author index

Bibliography index

Book index

Conference index

Corporate author index

The above indexes are cumulated at six-monthly intervals. The author and subject indexes are also cumulated at four-yearly intervals*.

● Do You Have Access to This Important Journal?

Does your library or information service provide you with access to this important journal? If not, ask your librarian to contact INSPEC for a free sample and subscription details or write to us direct.

(* four year cumulative indexes not included in annual subscription price)

Developments in distribution switchgear

The papers presented at the international conference on developments in distribution switchgear have now been published as number 168 in the IEE Conference Publication series. The Conference, held in London in November 1978, was sponsored by the IEE Power Division in association with the Institute of Electrical and Electronics Engineers and the Institute of Mathematics and its Applications.

Topics covered include arc interruption media, insulation materials and design, and switchgear design for industrial applications. Substation design and operational aspects, switch and fusegear arrangements, and testing approval and service experience are also covered.

28 papers, 120 pp., 297 x 210mm, photolitho, ISBN 0 85296 194 4, November 1978, soft covers, £8.50 UK, \$20.00 Americas, £10.00 Elsewhere.

Inquiries, and orders with remittances should be sent to:

Publication Sales Department,
Institution of Electrical Engineers,
PO Box 26, Hitchin,
Herts. SG5 1SA, England.

Orders for the Americas should be sent to:

The Institution of Electrical Engineers,
IEEE Service Center,
445 Hoes Lane,
Piscataway, NJ 08854, USA.

MISSING ISSUES? NEW SUBSCRIPTION?

Why not dramatically increase the effectiveness of your information resources by holding previous years copies of INSPEC Abstracts Journals?

Do you find that your collection of INSPEC Abstracts Journals has gaps — a missing index perhaps? Then why not fill those gaps with the appropriate back issues?

Back issues are surprisingly inexpensive and available from:-

Wm Dawson (Back Issues) Ltd
Cannon House
Folkestone
Kent

No space for back volumes? Why not convert your holdings to microfilm? We can give you a quote without any obligation on your part, just contact

CUMULATIVE INDEXES

Cumulative indexes are available for *Physics Abstracts*, *Electrical & Electronics Abstracts* and *Computer & Control Abstracts*, for both

authors and subjects. These cumulations generally cover a period of four years, with the exception of *Computer & Control Abstracts*

where the initial volume covered the period 1966-68. The table below shows the prices and periods for the two types of cumulative index.

| | PHYSICS ABSTRACTS | | ELECTRICAL & ELECTRONICS ABSTRACTS | | COMPUTER & CONTROL ABSTRACTS | |
|---------|-------------------|--------|------------------------------------|--------|------------------------------|--------|
| | Subject | Author | Subject | Author | Subject | Author |
| | £ | £ | £ | £ | £ | £ |
| 1955-59 | 20 | 20 | 15 | 20 | — | — |
| 1960-64 | 40 | 17 | 20 | 12 | — | — |

ORDERING PROCEDURE

THE AMERICAS

North (including Canada), Central and South

All orders from the above areas, and orders from members of Institute of Electrical and Electronics Engineers Inc. anywhere in the world, should be sent to Fulfillment Manager, Institute of Electrical & Electronics Engineers Inc., 445 Hoes Lane, Piscataway, N.J. 08854, USA. Telephone (201) 981 0060

日本のお客様にご案内申し上げます

日本国内に於けるINSPECの購入価格はすべて円建てとなっております。また刊行物はすべて航空便で配達されます。INSPEC刊行物の価格、その他についてのお問い合わせは最寄の支店取扱専門店または輸入総代理店様ユー・エス・エンジニアテック カンパニー 〒105東京都港区新橋1-13-12、TEL 03 (502) 6471 までご連絡ください。

REMAINDER OF THE WORLD

All remaining subscriptions should be sent to INSPEC Marketing Department, P.O. Box 26, Hitchin, Herts SG5 7RS, England. Telephone Hitchin 53331, Telex 825962, Telegrams IEE G.

OTHER INSPEC SERVICES

SDI

(Selective Dissemination of Information.) This is a service individually tailored to the requirements and interests of the engineer or research worker. Details of information relevant to the interest profile of the individual subscriber are selected from the data being processed for the INSPEC database. Information is dispatched weekly on 150 mm x 100 mm (6" x 4") cards.

TOPICS

This is an SDI service based on standard profiles. There are over 70 subjects covering high-activity areas of research and development. This is an inexpensive card service designed to alert engineers and researchers to the availability of literature within their subject area.

MAGNETIC TAPES

Tapes containing all the information included in the INSPEC publications are issued twice monthly. They enable the larger research and development organisations to produce their own internal information and current-awareness services.

Physics Abstracts

15th August 1981

Summary Classification

The full classification and contents are given at the front of the journal, followed by an **Alphabetical Index** to the subjects covered

00.00 General

- 01.00 Communication, Education, History and Philosophy
- 02.00 Mathematical Methods in Physics
- 03.00 Classical and Quantum Physics; Mechanics and Fields
- 04.00 Relativity and Gravitation
- 05.00 Statistical Physics and Thermodynamics
- 06.00 Measurement Science, General Laboratory Techniques, and Instrumentation Systems
- 07.00 Specific Instrumentation and Techniques of General Use in Physics

10.00 The Physics of Elementary Particles and Fields

- 11.00 General Theory of Fields and Particles
- 12.00 Specific Theories and Interaction Models; Particle Systematics
- 13.00 Specific Reactions and Phenomenology
- 14.00 Properties of Specific Particles and Resonances

20.00 Nuclear Physics

- 21.00 Nuclear Structure
- 23.00 Radioactivity and Electromagnetic Transitions
- 24.00 Nuclear Reactions and Scattering: General
- 25.00 Nuclear Reactions and Scattering: Specific Reactions
- 27.00 Properties of Specific Nuclei listed by Mass Ranges
- 28.00 Nuclear Engineering and Nuclear Power Studies
- 29.00 Experimental Methods and Instrumentation for Elementary-Particle and Nuclear Physics

30.00 Atomic and Molecular Physics

- 31.00 Theory of Atoms and Molecules
- 32.00 Atomic Spectra and Interactions with Photons
- 33.00 Molecular Spectra and Interactions with Photons
- 34.00 Atomic and Molecular Collision Processes and Interactions
- 35.00 Properties of Atoms and Molecules; Instruments and Techniques
- 36.00 Studies of Special Atoms and Molecules

40.00 Classical Areas of Phenomenology

- 41.00 Electricity and Magnetism; Fields and Charged Particles
- 42.00 Optics
- 43.00 Acoustics
- 44.00 Heat Flow, Thermal and Thermodynamic Processes
- 46.00 Mechanics, Elasticity, Rheology
- 47.00 Fluid Dynamics

50.00 Fluids, Plasmas and Electric Discharges

- 51.00 Kinetic and Transport Theory of Fluids; Physical Properties of Gases
- 52.00 The Physics of Plasmas and Electric Discharges

60.00 Condensed Matter: Structure, Thermal and Mechanical Properties

- 61.00 Structure of Liquids and Solids; Crystallography
- 62.00 Mechanical and Acoustic Properties of Condensed Matter
- 63.00 Lattice Dynamics and Crystal Statistics
- 64.00 Equations of State, Phase Equilibria, and Phase Transitions
- 65.00 Thermal Properties of Condensed Matter
- 66.00 Transport Properties of Condensed Matter (Nonelectronic)
- 67.00 Quantum Fluids and Solids; Liquid and Solid Helium
- 68.00 Surfaces and Interfaces; Thin Films and Whiskers

70.00 Condensed Matter: Electronic Structure, Electrical, Magnetic, and Optical Properties

- 71.00 Electron States
- 72.00 Electronic Transport in Condensed Matter
- 73.00 Electronic Structure and Electrical Properties of Surfaces, Interfaces, and Thin Films
- 74.00 Superconductivity
- 75.00 Magnetic Properties and Materials
- 76.00 Magnetic Resonances and Relaxation in Condensed Matter; Mossbauer Effect
- 77.00 Dielectric Properties and Materials
- 78.00 Optical Properties and Condensed Matter Spectroscopy and other Interactions of Matter with Particles and Radiation
- 79.00 Electron and Ion Emission by Liquids and Solids; Impact Phenomena

80.00 Cross-Disciplinary Physics and Related Areas of Science and Technology

- 81.00 Materials Science
- 82.00 Physical Chemistry
- 86.00 Energy Research and Environmental Science
- 87.00 Biophysics, Medical Physics, and Biomedical Engineering

90.00 Geophysics, Astronomy and Astrophysics

- 91.00 Solid Earth Geophysics
- 92.00 Hydrospheric and Atmospheric Geophysics
- 93.00 Geophysical Observations, Instrumentation, and Techniques
- 94.00 Aeronomy and Space Physics
- 95.00 Fundamental Astronomy and Astrophysics, Instrumentation and Techniques and Astronomical Observations
- 96.00 Solar System
- 97.00 Stars
- 98.00 Stellar Systems; Galactic and Extragalactic Objects and Systems; The Universe
